Revised December 2001

Community Tracking Study (CTS) Physician Survey, Round Two
Fact Sheet

Survey Details	
Sample	12,304 physicians in the contiguous U.S. providing direct patient care for at least 20 hours per week, excluding federal employees, specialists in fields in which the primary focus is not direct patient care, and foreign medical school graduates who are only temporarily licensed to practice in the U.S. The majority of the sample is clustered in 60 communities, with a smaller supplemental sample drawn from the entire contiguous U.S. Among those 12,304 physicians, 7,092 also appeared in the data from the Round One survey, providing a panel sample (for users of the Restricted Use File only).
Time period	August 1998 – November 1999
Content	Physician specialty Practice arrangements and ownership Physician time allocation Sources of practice revenue Level and determinants of physician compensation Physician provision of charity care Perception of ability to deliver care Career satisfaction Effects of care management strategies Various aspects of phyisicians' practice of medicine Physician race and ethnicity
Differences between the Round One and Round Two surveys	There were only minor differences between the two rounds. The Round Two survey collected information on physician race and ethnicity, although that information is heavily masked for confidentiality reasons except for users of the Restricted Use File. See Chapter 2 for details on other differences.
Types of estimates	
Geographic areas represented	These data are designed to allow the user to calculate nationally representative estimates. In addition, users of the Restricted Use File can calculate estimates for the 60 selected communities.
Round Two estimates	These data can be used for calculating cross-sectional estimates for Round Two.
Change estimates (cross-sectional and panel)	The Round Two data can be combined with the Round One data to calculate the difference across rounds. In addition, users of the Restricted Use File can combine the two rounds of data and then calculate estimates of change at the physician level for the panel sample of physicians.
Pooled estimates	To benefit from increased sample size, data from Round One and Round Two can be combined to calculate a single "pooled" estimate.

Community Tracking Study (CTS) Physician Survey, Round Two
Fact Sheet - *continued*

Using the Data Files	
Obtaining the data files and documentation.	The data files and documentation are available through the Inter-University Consortium for Political and Social Research (ICPSR). The web site is www.icpsr.umich.edu, and the ICPSR study number for the Round Two Physician Survey is 3267. The Public Use File can be downloaded at no cost directly from the ICPSR web site. The Restricted Use File is available to approved users only and is available at no or nominal fee. ICPSR provides the restricted data file on CD. To obtain permission to use the Restricted Use File, users must comply with conditions listed in the CTS Physician Survey Restricted Data Use Agreement, such as limiting data access to people specified in the agreement and destroying the data upon completion of the specified research project. Copies of the agreement and a description of the application process are available from the ICPSR web site.
Software requirements	Because the CTS Physician Survey has a complex sample design, most commonly used statistical software packages will not estimate standard errors correctly. Therefore, we provide standard error look-up tables and formulas to approximate standard errors. In addition, the user's guide for the Restricted Use File explains how to use one specialized software package (SUDAAN) to directly calculate standard errors.
Differences between the Public Use File and the Restricted Use File	The Public Use File contains less detailed information than the Restricted Use File in order to preserve the confidentiality of the survey respondents. The Public Use File has fewer variables, some of which have undergone more extensive editing than those on the Restricted Use File. The Public Use File doesn't contain information on the geographical area of the physician's practice. It also doesn't contain the information necessary for using statistical software programs that account for the complex survey design, which means that users must use the standard error look-up tables or formulas to derive approximate standard errors. Lastly, only the Restricted Use File contains information that allows the user to identify physicians that are part of both the Round One and Round Two samples.

What's New

Version	Date	Description of Changes
Release One	July 2001 December 2001	Original release Changes were made only to the User's Guide. A discussion was added about how to pool data from Round One and Round Two in order to increase sample size. No changes were made to the data file.

ACKNOWLEDGMENTS

This User's Guide and the accompanying Codebook and data file were produced by the Center for Studying Health System Change (HSC) in collaboration with its contractors, Mathematica Policy Research, Inc. (MPR) and Social and Scientific Systems, Inc. (SSS). Elizabeth Schaefer and Sally Trude of HSC provided general oversight, David Edson of MPR provided ongoing supervision and coordination to this project, and Gary Moore of SSS supervised the production of the data file and the Codebook.

The development of the data file, including editing, imputation, and new variable construction, was largely performed by Ellen Singer of SSS, with assistance from Valeriy Bakaushin of SSS. Survey weights and procedures for variance estimation were developed by John Hall, Frank Potter, and Barbara Lepidus Carlson of MPR. Guidance in the data file construction was provided by HSC staff members Marie Reed and Jeffery Stoddard. David Edson, Ellen Singer, and Marie Reed had primary roles in developing the data confidentiality procedures, with the assistance of Thomas Jabine, an independent data confidentiality consultant.

Barbara Lepidus Carlson was the primary author of Chapters 1 through 3 of the User's Guide. Ellen Singer was the primary author of Chapters 4 and 5. Barbara Lepidus Carlson wrote Appendix B, which explains the derivation of the standard error tables, with assistance from John Hall. John Hall developed the standard error look up tables in Appendix C, with the assistance of Gary Moore and Ellen Singer of SSS. David Edson participated in all components of the User's Guide development.

The Codebook was developed primarily by Ellen Singer, with assistance from Gary Moore, Marie Reed, Valeriy Bakaushin, and Nancy Odaka of SSS.

PREFACE

The Community Tracking Study (CTS) provides information to help policy makers and health care leaders make sound decisions. The CTS collects information on how the health system is evolving in 60 communities across the United States and the effects of those changes on people. Funded by the Robert Wood Johnson Foundation, the study is being conducted by the Center for Studying Health System Change (HSC).

The CTS relies on periodic site visits and surveys of households, physicians, and employers. One component of the CTS, the Physician Survey, provides information about source of practice revenue, problems physicians face in practicing medicine, how they are compensated and what effect various care management strategies have on their practices, as well as questions about their practice arrangements. This User's Guide gives researchers the information necessary for using the public use version of the data file containing information from the Round Two Physician Survey.

Data collection for the Round Two Physician Survey began in the summer of 1998 and was completed by the fall of 1999. An earlier version of the survey, Round One, was conducted in 1996 and 1997. Each survey was designed to allow separate cross-sectional estimates. Researchers can use each round of the CTS Physician Survey for separate cross-sectional analyses or use both rounds to study changes in the health care system over time.

The User's Guide presents background information about the CTS and the Round Two Physician Survey, explains how to select samples and weight variables, and discusses the correct approach to estimating variances. This discussion is followed by a description of variable construction and editing, and other information about the data file. A copy of the Round Two Physician Survey questionnaire appears in Appendix A. A discussion of the derivation of standard error look-up tables for use with the file is contained in Appendix B and Appendix C contains these tables. The *Community Tracking Study Physician Survey Public Use File: Codebook (Round Two, Release 1)* provides more detail on the file, including frequencies and definitions of variables. Information about the Round One Physician Survey Public Use File can be found in the *Community Tracking Study Physician Survey Public Use File: User's Guide (Round One)* and the *Community Tracking Study Physician Survey Public Use File: Codebook (Round One)*.

OBTAINING TECHNICAL ASSISTANCE

Information on the CTS Physician Survey, and the CTS in general, may be obtained through the HSC internet home page at http://www.hschange.org. The Public Use File and the latest documentation are available through the Inter-university Consortium for Political and Social Research at http://www.icpsr.umich.edu.

Technical assistance on issues related to the data file may be obtained by contacting the CTS Help Desk by e-mail at ctshelp@hschange.org or fax (202-863-1763).

CHAPTER 1

OVERVIEW OF THE COMMUNITY TRACKING STUDY AND THE PHYSICIAN SURVEY

This guide is intended to assist researchers in using the Community Tracking Study (CTS) Round Two Physician Survey Public Use File. The CTS is a national study of the rapidly changing health care market and the effects of these changes on people.[1] Funded by the Robert Wood Johnson Foundation, the study is being conducted by the Center for Studying Health System Change (HSC). Additional documentation and detailed information on the file layout and content are available in *Community Tracking Study Physician Survey Public Use File: Codebook (Round Two).* Information about other aspects of the CTS is available from HSC at www.hschange.org. Technical assistance on issues related to the data file may be obtained by contacting the CTS Help Desk by e-mail at ctshelp@hschange.org or fax (202-863-1763).

1.1. CTS OBJECTIVES

The CTS is designed to provide information to help policy makers and health care leaders make sound decisions. The CTS collects information on how the health system is evolving in 60 communities across the United States and the effects of those changes on people. Underway since 1996, the CTS is a longitudinal project that relies on periodic site visits and surveys of households, physicians and employers. While many studies have examined leading markets in California and Minnesota and analyzed local or selected data, there has been no systematic study of change in a broad cross-section of U.S. markets or analysis of the effects of those changes on service delivery, cost and quality. The Community Tracking Study is designed to provide sound empirical evidence that will inform the debate about health system change. The study addresses two broad questions that are important to public and private health decision-makers:

How is the health system changing? How are hospitals, health plans, physicians, safety net providers and other provider groups restructuring, and what key forces are driving organizational change?

How do these changes affect people? How are insurance coverage, access to care, use of services, health care costs and perceived quality of health care changing over time?

Focusing on communities is central to the design of the CTS. Understanding market changes requires studying local markets, including their culture, history and public policies relating to health care. HSC researchers randomly selected 60 communities stratified by region, community size and type (metropolitan-nonmetropolitan) to provide a representative profile of change across the United States.[2]

[1]An overview of the Community Tracking Study is contained in Kemper, et al. (1996).

[2]The CTS covers the contiguous 48 states. Alaska and Hawaii were not part of the study.

Of these communities, 12 are studied in depth, with site visits and survey samples large enough to draw conclusions about change in each community. These communities are a randomly selected subset of the sites that are metropolitan areas with more than 200,000 people and are referred to as the high-intensity sites.

1.2. ANALYTIC COMPONENTS OF THE COMMUNITY TRACKING STUDY

The CTS has qualitative and quantitative components. Case studies in the 12 high-intensity sites make up the qualitative component and surveys of households, physicians, and employers are the quantitative component. The first three rounds of comprehensive case studies of the health systems in the 12 communities are completed. The first round was conducted in 1996 and 1997, the second in 1998 and 1999, and the third in 2000 and 2001. The findings are available from HSC.[3] This information is complemented by survey data from these 12 communities and from 48 additional sites, listed in Table 1.1. In all 60 sites, HSC simultaneously conducted independent surveys of households and physicians, enabling researchers to study health insurance coverage, access to care, and physician practice patterns, among other issues. Another component of the CTS is the Followback Survey, in which the privately financed health insurance policies covering Household Survey respondents are "followed back" to the organization that administers the policy. The purpose of the Followback Survey is to obtain more detailed and accurate information about those private policies than Household Survey respondents could provide. A CTS survey of employers sponsored by the Robert Wood Johnson Foundation was conducted by RAND in 1996 and 1997.[4]

Data are being collected on a two-year cycle, allowing researchers to track changes in the health care system over time. The Round One Household and Physician surveys and case studies completed during 1996 and 1997 and the Followback Survey completed in 1997 and 1998 are the baseline. Data collection for the Round Two Household and Physician surveys began in 1998 and was completed in 1999. Round Two Followback Survey data collection was conducted during 1999 and 2000.

[3]Community reports from each round are available through the HSC web site at www.hschange.org.

[4]The Household and Physician surveys were conducted by HSC. The Employer Survey was conducted by RAND in collaboration with HSC. The surveys are available separately as both public and restricted use files. While these three surveys were conducted in the same communities, they were independent of one another and do not allow for the linking of persons, employers, or physicians.

TABLE 1.1

SITES SELECTED FOR THE COMMUNITY TRACKING STUDY

High-Intensity Sites	Low-Intensity Sites	
Metro areas >200,000 population	Metro areas >200,000 population	Metro areas <200,000 population
01-Boston (MA)	13-Atlanta (GA)	49-Dothan (AL)
02-Cleveland (OH)	14-Augusta (GA/SC)	50-Terre Haute (IN)
03-Greenville (SC)	15-Baltimore (MD)	51-Wilmington (NC)
04-Indianapolis (IN)	16-Bridgeport (CT)	
05-Lansing (MI)	17-Chicago (IL)	Nonmetropolitan Areas
06-Little Rock (AR)	18-Columbus (OH)	
07-Miami (FL)	19-Denver (CO)	52-West Central Alabama
08-Newark (NJ)	20-Detroit (MI)	53-Central Arkansas
09-Orange County (CA)	21-Greensboro (NC)	54-Northern Georgia
10-Phoenix (AZ)	22-Houston (TX)	55-Northeastern Illinois
11-Seattle (WA)	23-Huntington (WV/KY/OH)	56-Northeastern Indiana
12-Syracuse (NY)	24-Killeen (TX)	57-Eastern Maine
	25-Knoxville (TN)	58-Eastern North Carolina
	26-Las Vegas (NV/AZ)	59-Northern Utah
	27-Los Angeles (CA)	60-Northwestern Washington
	28-Middlesex (NJ)	
	29-Milwaukee (WI)	
	30-Minneapolis (MN/WI)	
	31-Modesto (CA)	
	32-Nassau (NY)	
	33-New York City (NY)	
	34-Philadelphia (PA/NJ)	
	35-Pittsburgh (PA)	
	36-Portland (OR/WA)	
	37-Riverside (CA)	
	38-Rochester (NY)	
	39-San Antonio (TX)	
	40-San Francisco (CA)	
	41-Santa Rosa (CA)	
	42-Shreveport (LA)	
	43-St. Louis (MO/IL)	
	44-Tampa (FL)	
	45-Tulsa (OK)	
	46-Washington (DC/MD)	
	47-West Palm Beach (FL)	
	48-Worcester (MA)	

Note: The numbers listed above are site identifiers and are provided in the Restricted Use data file as the variable SITEID.

1.3. THE PHYSICIAN SURVEY

The Physician Surveys, funded by the Robert Wood Johnson Foundation, were conducted under the direction of HSC. The Gallup Organization was the primary data collection contractor. Mathematica Policy Research, Inc. (MPR) managed the Gallup subcontract for HSC and was responsible for sample design, weighting, variance estimation and tracking of physicians who could not be located. Project Hope and CODA, Inc. assisted in developing the Round One survey instrument, including cognitive testing. Social and Scientific Systems, Inc. (SSS) converted the raw survey data into a data file suitable for analysis.

The Physician Survey instrument collected information on physician supply and specialty distribution; practice arrangements and physician ownership; physician time allocation; sources of practice revenue; level and determinants of physician compensation; provision of charity care; physicians' perception of their ability to deliver care and of career satisfaction; effects of care management strategies; and various aspects of physicians' practice of medicine. For primary care physicians (PCPs), the instrument also contained vignettes that provided clinical presentations for which there is no prescribed method of treatment. Except for minor changes (discussed below), the same survey instrument was used in Round One and Round Two of the Physician Survey.

The survey was administered completely by telephone, using computer-assisted telephone interviewing technology. Bilingual interviewers were used in the few cases where needed. Interviews with 12,280 physicians[5] were completed between August 1998 and November 1999.

The sample frame was developed by combining lists of physicians from the American Medical Association (AMA) and the American Osteopathic Association (AOA). About 75% of the Round One respondents were randomly selected for the Round Two survey, and a high percentage of those selected agreed to participate in the second round. There were 7,092 physicians who participated in both rounds of the survey.

1.4. PHYSICIAN SURVEY PUBLIC USE FILE AND RESTRICTED USE FILE

Two versions of the CTS Physician Survey data are available to researchers: the Restricted Use File and the Public Use File. The ***Restricted Use File*** may be used only under the conditions listed in the *Community Tracking Study Physician Survey Restricted Data Use Agreement.* This agreement provides details on ownership of the data, when the data may be obtained and by whom, how the data may be used, the data security procedures that must be implemented, and the sanctions that will be imposed in the case of data misuse. Researchers must specifically apply for use of the Restricted Use File. Copies of the agreement and a description of the application process are available from the ICPSR web site at www.icpsr.umich.edu.

[5] There are 12,304 records on the file; 24 physicians were sampled twice and therefore appear on the file twice, even though they completed only one interview each. Sampling weights were constructed so that duplicate records do not bias results. Consequently, researchers should not delete the duplicate records.

The Restricted Use File is provided to researchers for use on only a specific research project (new applications would be required for subsequent analyses using the data) and for a limited time period, after which all copies of the data must be destroyed. Moreover, researchers using the Restricted Use File may be required to undertake costly or inconvenient security measures. Researchers who are interested only in producing site-level means from the physician data, whether to perform analysis using a site-level file or to merge onto one of the other CTS component surveys, may choose instead to wait for the summary (site-level mean) file. Researchers are encouraged to review documentation for both the Public Use and Restricted Use files, available from ICPSR at www.icpsr.umich.edu, as well as the requirements of the *Community Tracking Study Physician Survey Restricted Data Use Agreement*, before deciding which file will meet their needs.

The ***Public Use File*** is available from ICPSR. Researchers need not specifically apply for use of the Public Use File. It is suitable for most researchers who wish to perform analysis at the national level and do not anticipate using the site-level information in their analysis. The Public Use File does not support analysis at the site level or analysis that uses site-level information. Although it contains all of the same observations as the Restricted Use File, several variables have been deleted or modified slightly for data confidentiality reasons (see below). Note that, unlike the Restricted Use File, the Public Use File does not contain information that allows the user to identify the panel sample of physicians who are part of both the Round One and Round Two samples. Moreover, information necessary for using statistical software programs that account for the survey design is not included in the Public Use File, necessitating the use of standard error look-up tables or formulas contained in Chapter 4 to derive approximate standard errors. Separate documentation on the Restricted Use File is available from ICPSR at www.icpsr.umich.edu.

As stated above, this Public Use File does not contain certain data that are available on the Restricted Use File version of the Physician Survey. Other variables in the Public Use File were modified somewhat to ensure the confidentiality of survey respondents. These modifications are described in Chapter 5. Table 1.2 lists the variables available on the Public and Restricted Use versions of the data file. In this table, a different name for the same variable on the Public Use and Restricted Use files (the Public Use name ends in "X") indicates that the data for this variable underwent additional editing for confidentiality.

TABLE 1.2

VARIABLES ON THE PHYSICIAN RESTRICTED USE AND PUBLIC USE FILES

Restricted Use Name	Public Use Name	Variable Label (on Restricted Use File)
Survey Administration Variables		
PHYSIDX	PHYSIDX	PH2:Physician identification number
R1PHYIDX	n/a	PH2:Value for PHYSIDX in Round One

Notes: 'n/a' identifies variables that are not available on the CTS Physician Survey Public Use File. Variable label contains a brief description of the variable. In some cases, the label also provides information on the source of the variable (e.g., PH2 for the Round Two Physician Survey) and the question number (e.g., 'A6' for Section A, Question 6).

CHAPTER 2

THE STRUCTURE AND CONTENT OF THE COMMUNITY TRACKING STUDY PHYSICIAN SURVEY

The Physician Survey was administered to a sample of physicians in the 60 CTS sites and to an independent national sample of physicians. The survey's three-tiered sample design makes it possible to develop estimates at the national and community (site) levels.

- The first tier is a sample of 12 communities from which a large number of physicians in each community were surveyed. The sample in each of these "high-intensity" sites is large enough to support estimates in each site.
- The second tier is a sample of 48 communities from which a smaller sample of physicians in each community was surveyed. This sample of "low-intensity" sites allows us to validate results from the high-intensity sites and permits findings to be generalized to the nation. The first and second tiers together are known as the *site sample*.
- The third tier is a smaller, independent national sample. Known as the *supplemental sample*, this sample augments the site sample and substantially increases the precision of national estimates with a relatively modest increase in the total sample size.

Because a physician's practice location would allow identification of specific respondents, location identifiers are not provided in the Public Use File. This file therefore supports only national estimates, while the Restricted Use File supports both national and site-level estimates.

This chapter describes the sample design, the process of conducting the survey, the survey content, survey administration and processing, and the sample and weighting variable to be used for analyses using the Public Use File. The background information on sample design (Sections 2.1 and 2.2) is provided for those who are interested; however, it is not necessary to read these sections in order to use the Public Use File.

2.1. CTS SAMPLE SITES

The primary goal of the CTS is to track health system change and its effects on people, accounting for characteristics of local markets. The first step in designing the CTS sample, therefore, was to determine the appropriate communities, or sites, to study. Three issues were central to the sample design: the definition of the sites, the number of sites, and the selection of the sites.

2.1.1. Definition of Sites

The sites encompass local health care markets. Although there are no set boundaries for these local markets, the intent was to define areas such that residents predominately used health care providers in their area and providers served predominately area residents. We generally defined sites as metropolitan statistical areas (MSAs) as defined by the Office of Management and

Budget or the nonmetropolitan portions of economic areas as defined by the Bureau of Economic Analysis (BEAEAs).[6]

2.1.2. Number of Sites

The next step in creating the site sample was to determine the number of high-intensity sites. In making this decision, we considered the tradeoffs between data collection costs (case studies plus survey costs) and the research benefits of a large sample of sites. The research benefits of a larger number of sites include a greater ability to empirically examine the relationship between system change and its effect on care delivery and consumers and to make the study findings more "generalizable" to the nation. Despite the cost advantages of conducting intensive case studies in fewer sites, focusing on a smaller number of communities makes it more difficult to distinguish between changes of general importance and changes or characteristics unique to a community. Solving this problem by increasing the number of case study sites would make the cost of data collection and analysis prohibitively high.

We chose 12 sites for intensive study and added 48 sites for less-intensive study. These 60 high-intensity and low-intensity sites form the *site sample*. Although there was no formal scientific basis for choosing 12 high-intensity sites, this number reflects a balance between the benefits of studying a range of different communities and the costs of doing so. The addition of 48 low-intensity sites solves the problem of limited generalizability associated with only 12 sites and provides a benchmark for interpreting how representative the high-intensity sites are.

2.1.3. Site Selection

Once the number of sites for the site sample had been determined, we selected the actual sites. Shown previously in Table 1.1, the 60 sites, or "primary sampling units," were chosen for the first stage of sampling. Sites were sampled by stratifying them geographically by region and selecting them randomly, with probability in proportion to their 1992 population. There were separate strata for small MSAs (population of less than 200,000) and for nonmetropolitan areas. The high-intensity sites were selected randomly from MSAs with a 1992 population of 200,000 or more. Of the low-intensity sites, 36 are large metropolitan areas (also having a 1992 population of 200,000 or more), 3 are small metropolitan areas (population of less than 200,000), and 9 are nonmetropolitan sites. The *Community Tracking Study Site-County Crosswalk*, available through ICPSR at www.icpsr.umich.edu, identifies the specific counties, by FIPS code, that make up each CTS site. This sampling approach provided maximum geographic diversity, judged critical for the 12 high-intensity sites in particular, and acceptable natural variation in city size and degree of market consolidation.[7]

Together, the high-intensity and low-intensity sites account for about 90 percent of all Round Two survey respondents and can be used to make national estimates. The sample of high-intensity sites may also be used to make site-specific estimates for these twelve sites. However,

[6]For more details on the definition of CTS sites, refer to Metcalf, et al. (1996).

[7]Additional information about the number of sites and the random selection of the site sample is available in Metcalf et al. (1996).

the small sample size for each low-intensity site means that site-specific estimates for these sites will not be precise enough to support separate site analyses.

2.2. ADDITIONAL SAMPLES AND BETTER NATIONAL ESTIMATES

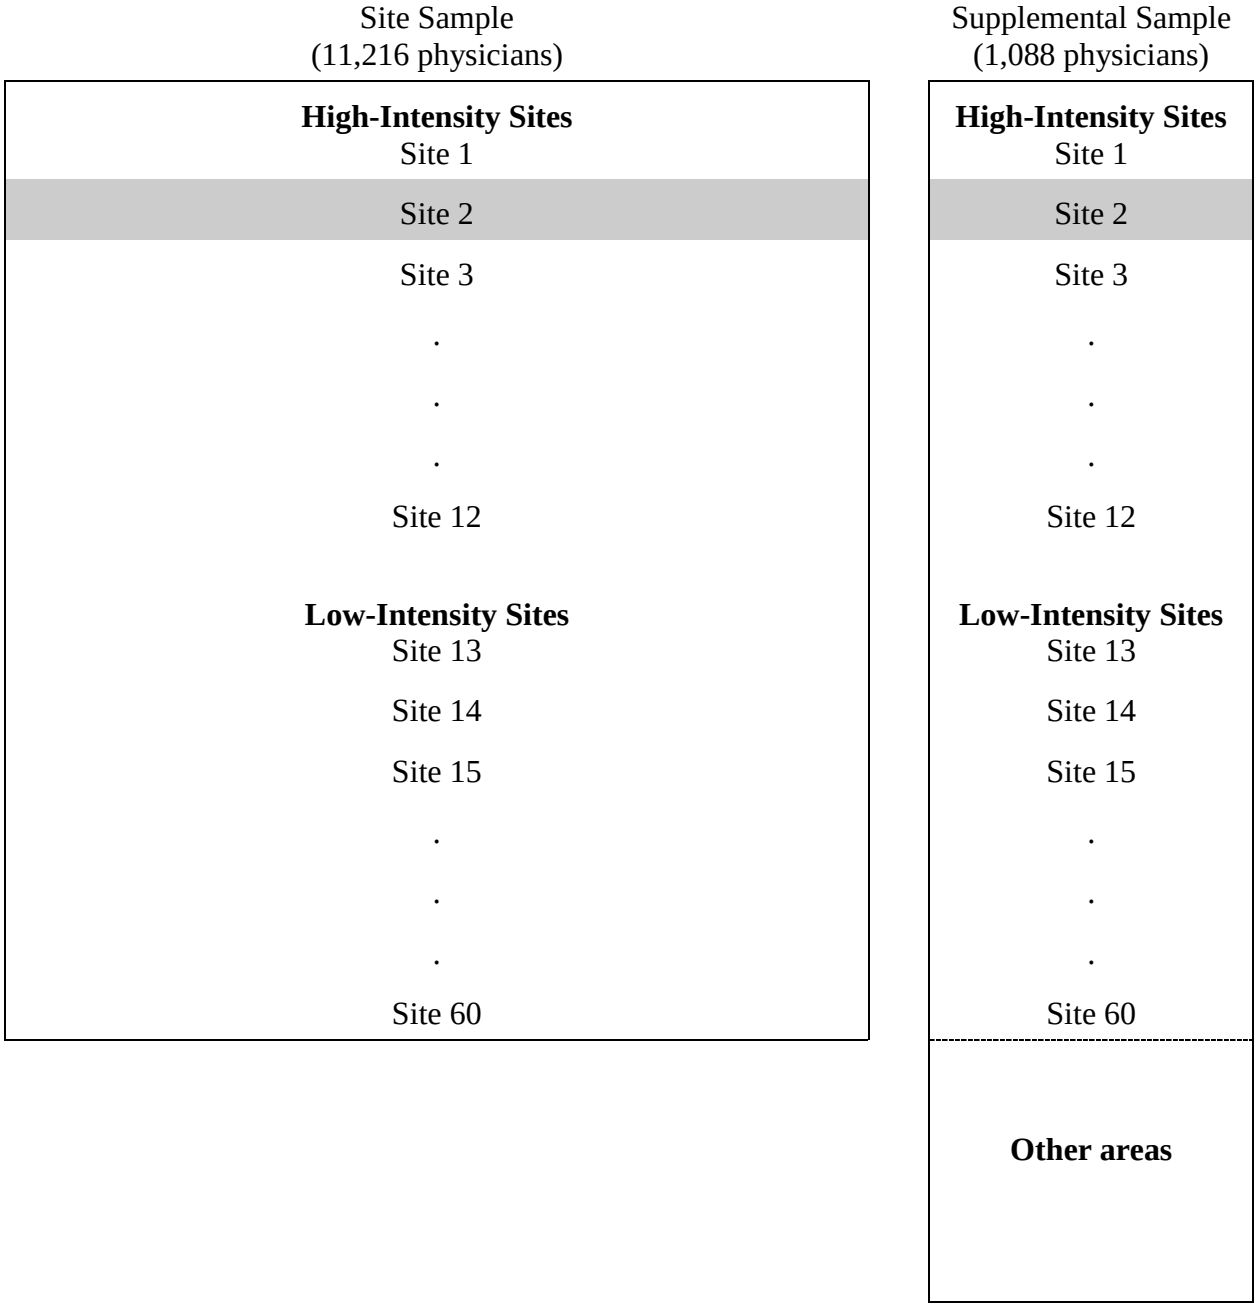
Although the site sample alone will yield national estimates, the estimates will not be as precise as they could have been if more communities had been sampled or had the sample been a simple random sample of the entire U.S. population. The *supplemental sample*, the third tier in the design of the CTS Physician Survey sample, was added to increase the precision of national estimates at a relatively small incremental increase in survey costs.

The supplemental sample is a relatively small, nationally representative sample made up of physicians randomly selected from the 48 states in the continental United States. It is stratified by region but essentially uses simple random sampling techniques within strata. When it is added to the site sample to produce national estimates, the resulting sample is called the *combined sample*. Because component samples are not identified, all analyses using the Public Use File are based on the combined sample.

Figure 2.1 illustrates the sample design. The shaded area shows the cases sampled in site 2 as part of the site sample and the supplemental sample cases that happened to fall within the site 2 boundaries.

FIGURE 2.1

THE CTS PHYSICIAN SAMPLE STRUCTURE



2.3. CONDUCTING THE SURVEY

After selecting the sample sites, we randomly selected physicians within each site. In the Round One Physician Survey, the AMA and the AOA constructed the sample frames and they drew the samples based on specifications provided to them. We also randomly selected physicians in this manner for the supplemental sample. In the Round Two Physician Survey, we obtained sample frames from the AMA and the AOA, but selected the sample ourselves.

In the Round Two Physician Survey, the sample design involved randomly selecting both physicians who were part of the Round One Survey and physicians who were not. This was true for both the site sample and the supplemental sample. Our goals in sampling the Round One physicians in Round Two were to improve precision for estimates of overall change between the two rounds and to reduce costs. Furthermore, by sampling Round One physicians for Round Two, we were able to create a panel, allowing us to track changes for individual physicians between the two rounds. Our goal in also including physicians who were not part of the Round One sample was to account for the fact that the re-interviewed Round One physicians might not be fully representative of all physicians. In the final sample of physicians for Round Two, about 58 percent also participated in the Round One survey.

2.3.1. Eligible Physicians

As the source for our sampling frame, we obtained the April 1998 version of the AMA Masterfile (which includes nonmembers) and the AOA membership file. To meet the initial eligibility criteria for sampling, physicians on the frame had to have completed their medical training,[8] be practicing in the contiguous United States, and be providing direct patient care for at least 20 hours per week.[9] Among those deemed initially eligible, the following types of physicians were specifically designated as ineligible for this survey and were removed from the frame:

- Specialists in fields in which the primary focus is not direct patient care[10]
- Federal employees
- Graduates of foreign medical schools who are only temporarily licensed to practice in the United States

[8] Residents, interns, and fellows were considered to be still in training.

[9] This criteria resulted in the exclusion of inactive physicians and physicians who were not office- or hospital-based (teachers, administrators, researchers, etc.).

[10] Radiology (including diagnostic, nuclear, pediatric, neuro-, radiation oncology, radiological physics, vascular, and interventional); anesthesiology; pain management; pain medicine; palliative medicine; pathology (including anatomic, clinical, dermato-, forensic, neuro-, chemical, cyto-, immuno-, pediatric, radioisotophic, selective); medical toxicology; aerospace medicine and undersea medicine; allergy and immunology/diagnostic laboratory; bloodbanking/transfusion medicine; clinical and laboratory dermatological immunology; forensic psychiatry; hematology; legal medicine; medical management; public health and general preventive medicine; nuclear medicine; clinical pharmacology; sleep medicine; other specialty; unspecified specialty.

We did not attempt to survey those who specifically requested to the AMA that their names not be released to outsiders. These physicians were later classified as nonrespondents for the purpose of weighting adjustments for nonresponse.

2.3.2. Stratification of Physician Sample Frames

Once we constructed our list of eligible physicians, we classified each physician on the list as either a primary care physician (PCP) or a non-primary care physician (non-PCP). PCPs were defined as those with a primary specialty of family practice, general practice, general internal medicine, internal medicine/pediatrics, or general pediatrics. All others with survey-eligible specialties were classified as non-PCPs.

After combining the AMA and AOA lists, we developed two sampling frames: one for the site sample and one for the supplemental sample. The physician's location for sampling purposes was determined by the AMA/AOA preferred mailing address. For the site sample, we included only those physicians whose preferred mailing address fell within the boundary of one of the 60 sites. Within each site, we selected a probability sample of PCPs and a probability sample of non-PCPs, further stratified by Round One disposition, and based upon an optimal sample-allocation plan. The plan resulted in 8 strata in each site.[11] PCPs were oversampled in the site sample.

For the supplemental sample, the sample frame was first divided into the following 10 geographic strata:

1. New England (CT, ME, MA, NH, RI, VT)
2. New York
3. Middle-South Atlantic (DE, NJ, PA, WV)
4. South Atlantic (DC, GA, MD, NC, SC, VA)
5. East South Central (AL, FL, KY, MS, TN)
6. West South Central (AR, LA, MO, OK, TX)
7. East North Central (IN, MI, OH)
8. North Central (IL, IA, MN, WI)
9. Mountain-Pacific (AZ, CO, ID, KS, MT, NE, NV, NM, ND, SD, OR, UT, WY, WA)
10. California

We selected a stratified random sample of physicians, independent of the site sample, where eight strata were defined within each of the 10 geographical strata, as defined above for the site sample. A probability sample was drawn within each of these strata.

Because the site and supplemental samples were drawn independently, it was possible for some physicians to be selected into both samples; in fact, 24 physicians were selected twice in Round Two. These twice-selected physicians were only interviewed once, but they appear as two different records on the file. Each has a unique identifier and was dealt with appropriately in the

[11] The eight strata were defined by two categories for physician type (PCP and specialist) and four categories for Round One disposition (not in Round One sample frame; in Round One sample frame but not sampled for Round One; sampled for Round One but did not complete Round One interview; and completed Round One interview).

weighting process. Thus, as is mentioned in Chapter 1, researchers do not need to be concerned about deleting duplicate records.

2.3.3. Physicians Excluded from the Survey

Some physicians thought to be eligible based on the sample frame information were later classified as ineligible based on survey responses. This happened if it turned out that the physician was still in training, provided direct patient care for less than 20 hours per week, practiced in an excluded specialty, was a federal employee, or was deceased. These ineligible physicians are not included on the file.

2.4. SURVEY CONTENT

Respondents to the survey were questioned about the following:

- Physician supply and specialty distribution
- Physician time allocation
- Practice arrangements and ownership
- "Gatekeeping"/medical care management strategies/scope of care
- Practice styles (PCPs only)
- Ability to provide care/ability to obtain needed services for patients/acceptance of new patients with various types of insurance
- Practice revenue
- Physician compensation
- Race/ethnicity

No proxy respondents were allowed for the Physician Survey. All physicians responded to the interview for themselves. Table 2.1 shows the topics covered in the survey in more detail. Detailed documentation for the computer-assisted telephone interview program, the equivalent of a survey instrument, is provided as Appendix A.

2.4.1. Differences Between Round One and Round Two Content

The survey instruments used in Round One and Round Two were similar, but not identical. The differences include:

- The Round One question on the percentage of time spent in physician's main practice was dropped from the survey for Round Two.
- Information on the physician's race and ethnicity were collected in Round Two. This information was not collected in Round One.

- The Round Two instrument included questions on whether a group practice was single- or multi-specialty, and if it was multi-specialty, whether it included both primary care physicians and specialists. That information was not collected for Round One.

Other Round Two changes were made for survey administration purposes.

2.5. SURVEY ADMINISTRATION AND PROCESSING

The survey was administered completely by telephone, using computer-assisted telephone interviewing technology. As described earlier, all physicians were selected from list frames received from the AMA and the AOA. The survey was fielded between August 1998 and November 1999. For PCPs, the average interview length was 21 minutes; for non-PCPs, the average length was 17 minutes.

The total number of completed interviews was 12,280,[12] with a response rate among eligibles of 60.9 percent. Physicians were sent advance letters from the Robert Wood Johnson Foundation and were offered a $25 honorarium for participating in the survey, with the option of forwarding the honorarium to a charity.

2.6. ANALYSIS USING THE PHYSICIAN SURVEY

The Round Two Physician Survey Public Use File can be used to make national estimates for physicians in 1998-1999. As described below, it can also be combined with the data from Round One to make national estimates of change between Round One and Round Two or to benefit from increased sample size.

The data file is a physician-level file; that is, it includes one data record for each physician responding to the survey. The file contains all physicians from the site and supplemental samples combined (n=12,304). The weight variable provided on this file is WTPHY4, which allows for making national estimates. This weight is based on the probability of selection within the sampled site or stratum.[13]

Using the Public Use File, you can conduct physician-level analyses that involve the study of physicians nationwide (including, for example, subgroups such as PCPs or non-PCPs, U.S.- or foreign-trained physicians, or physicians in large cities). However, you will not be able to estimate a model that contains explanatory variables that are site characteristics (e.g., site-level means from any CTS component survey) because this would require site identifiers that are not supplied on the Public Use File.

---

[12]There are 12,304 records on the file because 24 physicians were selected twice for the survey and appear twice on the file, even though they were only interviewed once. Each of these 24 physicians is represented by two records, each with the same survey data but with different weights.

[13]Refer to Potter, F. et al, "Report on Survey Methods for the Community Tracking Study's 1998-1999 Round Two Physician Survey" (which is a forthcoming HSC technical publication, available at www.hschange.org) for more details on the definitions and construction of the weight variables, including probabilities of selection and adjustments for physician nonresponse.

2.6.1. Using Data from the Two Rounds

As discussed earlier, some physicians that were part of the Round One sample are also part of the Round Two sample. To protect the confidentiality of the respondents, the Public Use File does not provide the information necessary to identify these physicians, or even to take advantage of the efficiencies in the overlapping sample design when producing estimates involving data from both rounds. To obtain information on those linkages, and to potentially get more precise estimates (by specifying which observations came from the same sites and strata, thereby generally controlling for more random noise), you would need to use the Restricted Use File.

2.6.2. Estimating Changes Between Round One and Round Two

To estimate the change in an attribute between the two rounds, you should calculate separate weighted estimates for each round and then compare them. For each round's estimate, you should look up the appropriate standard error from the tables provided in each round's Public Use File User's Guide. Because the variance of a sum or difference of estimates is equal to the sum of the variances of the individual estimates (if we ignore any covariances between the two estimates), we get the following formula for the standard error of the difference between a Round One and a Round Two estimate:

$$s.e._{diff} = \sqrt{(s.e._{Rd1})^2 + (s.e._{Rd2})^2}$$

where:

$s.e._{Rd1}$ = standard error for the Round One estimate, based on the standard error tables in the User's Guide for the Round One Physician Survey

$s.e._{Rd2}$ = standard error for the Round Two estimate, based on the standard error tables in the User's Guide for Round Two Physician Survey

You can then run a z-test for differences using the above standard error in the denominator of the z-statistic. To account for the covariance between the estimates for the two rounds, researchers need to use the SUDAAN parameters that are available only on the restricted use version of this file.

2.6.3. Pooling Data to Increase Sample Size

The purpose of combining or "pooling" data from Round One and Round Two is to increase sample size and therefore the precision of a cross-sectional estimate, which is especially desirable for analyses of certain smaller subgroups. This approach is appropriate only if you can assume that the variable of interest did not change substantially between the two rounds.

Suppose that you would like to estimate the pooled mean or proportion for a variable. Combine the two rounds of data into a single data set, with a separate observation for each physician in each round of data. Calculate the estimate (mean or proportion) using the weight WTPHY4. To determine the standard error of that pooled estimate, use the following formula (which requires additional calculations in order to obtain a separate estimate for each round).

$$s.e._{pooled-estimate} = \sqrt{(w_1^2 \cdot s.e._{Rd1}^2) + (w_2^2 \cdot s.e._{Rd2}^2)}$$

where:

$s.e._{Rd1}$ = standard error for the Round One estimate, based on the standard error tables in the User's Guide for the Round One Physician Survey
$s.e._{Rd2}$ = standard error for the Round Two estimate, based on the standard error tables in the User's Guide for Round Two Physician Survey
w_1 = (sum of Round 1 weights) / [(sum of Round 1 weights) + (sum of Round 2 weights)]
w_2 = (sum of Round 2 weights) / [(sum of Round 1 weights) + (sum of Round 2 weights)]

More formally: For i =1 or 2, let w_{ij} represent the weight for observation j in Round i, and let n_i represent your sample size in Round i.

$$w_i = \frac{\sum_{j=1}^{n_i} w_{ij}}{\sum_{j=1}^{n_1} w_{1j} + \sum_{j=1}^{n_2} w_{2j}}$$

TABLE 2.1

CONTENTS OF THE PHYSICIAN SURVEY

Topic	Description
Physician Supply and Specialty Distribution (Questionnaire Section A)	
Eligibility for survey	Federal employee Less than 20 hours/week Excluded specialty
Practice information	Number of practices Location of primary practice Year began medical practice
Specialty and certification	Primary specialty Board eligibility and certification
Satisfaction	Current level of satisfaction with overall career in medicine
Physician Time Allocation (Questionnaire Section B)	
In 1997, weeks worked	Number of weeks practiced medicine in 1997
Hours worked during last complete week of work	Hours worked in medicine during last complete week of work Hours spent in direct patient care during last complete week of work
Charity care in the last month	Hours spent in charity care in the last month
Practice Arrangements and Ownership (Questionnaire Section C)	
Ownership of practice	Respondent ownership Other owners Whether physician was part of a practice that was purchased during the past two years
Practice description	Type of practice Number of physicians employed Number of non-physician medical practitioners employed

TABLE 2.1

CONTENTS OF THE PHYSICIAN SURVEY
(Continued)

Gatekeeping / Medical Care Management Strategies / Scope of Care (Questionnaire Section D)	
Medical care management	Effect of various techniques on practice of medicine
PCPs	Percentage of patients for whom physician acts as gatekeeper Change in severity or complexity of patients' conditions for which care is provided without referral to specialists Appropriateness Change in number of referrals made
Non-PCPs	Changes in complexity or severity of patients' conditions at time of referral Appropriateness Change in number of referrals received
Practice Styles of Primary Care Physicians (Questionnaire Section E)	
PCPs	Clinical descriptions of patient histories for which physician is asked to state the percentage for whom s/he would recommend the course of action specified in the vignette.
Ability to Provide Care / Ability to Obtain Needed Services for Patients / Acceptance of New Patients with Various Types of Insurance (Questionnaire Section F)	
Level of agreement with statements regarding:	Having adequate time with patients Freedom to make clinical decisions Ability to provide high-quality care Level of communications with specialists/primary care physicians Ability to maintain continuing relationships with patients Ability to obtain a variety of specified services for patients Acceptance of new patients insured by Medicare, Medicaid, private insurance

TABLE 2.1

CONTENTS OF THE PHYSICIAN SURVEY
(Continued)

Topic	Description
Practice Revenue (Questionnaire Section G)	
Percentage of practice revenue from:	Medicare Medicaid Managed care Paid on a capitated or other prepaid basis Largest managed care contract Largest contract that is capitated or prepaid
Number of managed care contracts	Number of managed care contracts
Physician Compensation and Race/Ethnicity (Questionnaire Section H)	
Physician compensation	Whether physician is salaried Physician eligible to earn bonus or incentive income Factors used by practice to determine compensation
1997 income	Percentage of 1997 income earned in the form of bonuses, returned withholds, or other incentive payments Amount of income in 1997
Race/ethnicity	Hispanic origin Race

CHAPTER 3

DERIVING APPROPRIATE VARIANCE ESTIMATES

Some element of uncertainty is always associated with sample-based estimates of population characteristics because the estimates are not based on the full population. This sampling error is generally measured in terms of the standard error of estimate, or its sampling variance,[14] which is an indicator of the precision of an estimate. Estimates of the standard errors are necessary to construct confidence intervals around estimates and to conduct hypothesis tests.

Like many other large national surveys, the sample design for the CTS Physician Survey uses stratification, clustering, and oversampling. to provide the basis for making national and site-level (high-intensity sites) estimates. Specialized techniques are therefore required for estimating sampling variances when the CTS data are used. This chapter explains how to estimate standard errors that account for the sample design. We discuss why standard errors resulting from commonly used statistical software packages should not be used to make estimates from this survey. Because the Public Use File does not provide enough information to allow the use of specialized statistical software designed to estimate variances for survey data estimates, we provide standard error look-up tables and formulas to approximate standard errors (see Appendix C). These tables and formulas can be used to obtain, for some types of estimates, approximate standard errors that account for the survey design.

3.1. THE LIMITATION OF STANDARD STATISTICAL SOFTWARE

Standard statistical packages compute variances using formulas that are based on the assumption that the data are from a simple random sample taken from an infinite population. Although the simple random sample variance may approximate the sampling variance in some surveys, it is likely to substantially underestimate the sampling variance in a survey with a design like that of the CTS. For the CTS, the sampling variance estimate is a function of the sampling design and the population parameter being estimated; it is called the "design-based sampling variance."

Departures from a simple random sample design result in a "design effect" (*Deff*), which is defined as the ratio of the sampling variance (*Var*) given the actual survey design to the sampling variance of a hypothetical simple random sample (*SRS*) with the same number of observations. Thus:

$$Deff = \frac{Var\ (actual\ design\ with\ n\ cases)}{Var\ (SRS\ with\ n\ cases)}$$

[14]The sampling variance, which is the square of the standard error, is a measure of the variation of an estimator attributable to having sampled a portion of the full population of interest using a specific probability-based sampling design. The classical population variance is a measure of the variation among the population, whereas a sampling variance is a measure of the variation of the *estimate* of a population parameter (for example, a population mean or proportion) over repeated samples. The population variance is different from the sampling variance in the sense that the population variance is a constant, independent of any sampling issues, whereas the sampling variance becomes smaller as the sample size increases. The sampling variance is zero when the full population is observed, as in a census.

A design effect equal to one means that the design did not increase or decrease the sampling variance relative to a simple random sample. A design effect of greater than one means that the design increased the sampling variance; that is, it caused the estimate to be less precise. A design effect of less than one means that the net effect of the sample design was to decrease the variance (i.e., to make the estimate more precise). The standard error of an estimate can be expressed as the standard error from a simple random sample with the same number of observations, multiplied by the square root of the design effect.

Over a representative set of CTS Physician Survey variables, the average design effect for physician-level national estimates using the combined sample is about 1.84. This means that the standard error is, on average, about 35 percent higher than it would have been had the same number of cases been selected using a simple random sample. The design effect of 1.84 also means that the precision of the CTS (with 12,304 observations) is equal to that of a simple random sample with a size of about 6,687. Note that the design effect is generally lower for subclasses of the population because there is less clustering of observations.

Because most of the variables in the CTS Physician Survey have a design effect greater than one, we present standard error look-up tables and formulas giving approximate standard errors that account for the survey design. The Physician Survey Restricted Use File is required to use specialized software (such as SUDAAN) to directly estimate standard errors that take into account the survey design.

3.2. TABLES OF STANDARD ERRORS AND DESIGN EFFECTS

Tables C.1 through C.23 in Appendix C give approximate standard errors for various types of estimates and sample sizes. The standard error will vary depending on which variable is used and on the physician subgroup upon which the estimate is based (if any). Appendix B explains how these standard errors were derived and what variables were used in the modeling process.[15]

These 23 tables are for national estimates: 12 are for percentage estimates and 11 are for mean estimates of "quasi-continuous" variables (defined below). Many tables are included for specific subgroups of physicians, defined as follows:

- All primary care physicians (PCPFLAG=1)
- All non-primary care physicians (PCPFLAG=0)
- Internal medicine physicians (SPECX=1)
- Family/general practice physicians (SPECX=2)

[15]As explained in Appendix B, certain estimates with too small a sample size, too high a relative standard error, or too small or too large a design effect were excluded from the regression models upon which these tables are based. Before using one of the tables, check to make sure that your particular estimate has a sufficient sample size (greater than 100).

- Pediatricians (SPECX=3)
- Medical specialists, including psychiatrists (SPECX=4,6)
- Surgical specialists, including OB-GYNs (SPECX=5,7)
- Physicians in solo or two-person practice (PRCTYPE=1)
- Physicians in group practice (three or more) (PRCTYPE=2)
- Physicians in other practice settings (PRCTYPE=3,4,5,6)
- Physicians in practice with high revenue from managed care (above the median for PMC)
- Physicians in practice with low revenue from managed care (at/below the median for PMC)

For some types of estimates, we did not provide tables specific to some of these subgroups, either because the model used to develop the table was not significant for that subgroup, or because the estimates for that subgroup were not different enough to merit their own table (see Appendix B). Specifically, for mean estimates of quasi-continuous variables, there is no table for non-primary care physicians or surgical specialists. For quasi-continuous mean estimates limited to these physicians (or a subset of these physicians), you should use the table for all physicians (Table C.13).

If you are interested in a subset of physicians not listed above, you can use the table for all physicians. If you are interested in a subset of one of the subgroups defined above, use the table associated with that subgroup (see example in the next section).

These subgroups refer to the *denominator* of your estimate, not the numerator. For example, if you are estimating the percentage of physicians who are PCPs, you would use the table for all physicians (Table C.1), not the table specific to PCPs (Table C.2).

3.2.1. National Percentage Estimates

Tables C.1 through C.12 give approximate standard errors for percentage estimates at the national level. These tables are to be used for categorical or ordinal variables. To use these tables, you must have produced percentage estimates using any standard statistical package and the appropriate weight variable. You can obtain standard error estimates from each table for percentages based on the population of physicians, or any subset of the population, represented in the table. If in your estimate you are subsetting to one of the 12 subgroups defined above (or any subset within that subgroup), use the table specific to that subgroup whenever provided.

For example, if you are making a percentage estimate based on only female physicians, you would use the table for "all physicians" because there is no table specifically for females. If you are making a percentage estimate based on female internists or internists in general, you would use the table for "all PCP physicians" because there is no table specifically for percentage estimates of internists. For female pediatricians or pediatricians in general, you would use the table for "general pediatricians." Using the row associated with the unweighted sample size of

the subset, you can obtain approximate standard errors for any weighted percentage estimates for that subset.[16]

Suppose you are interested in the national percentage of female PCP physicians who are board certified. We know that the unweighted number of female PCP physicians is 2,100 and that the estimated percentage (weighted) of female PCP physicians who are board certified nationally is about 87 percent. With this information in mind, you would go to the national table for PCP physicians (Table C.2) and find the row in which sample size is equal to 2,000 and the column in which the percentage is equal to 15 or 85 percent. The approximate standard error of this estimate would be 1.06 percent. Although the table is based on all PCP physicians, you can easily determine standard errors for a subset of PCP physicians (in this case, females) by using the row corresponding to the number of records for the PCP subset of interest.

3.2.2. National Mean Estimates of "Quasi-Continuous" Variables

While most of the variables on the file are categorical or ordinal, many correspond to responses expressed in terms of percentages; for example, PMCAID is the percentage of practice revenue from Medicaid. Because these responses are bounded by 0 and 100, we call the corresponding variables "quasi-continuous" and have produced standard error tables for their means separately from the means of other variables. Note that we are estimating a mean of a response that was expressed by each physician as a percentage; we are not estimating a percentage. Approximate standard errors for national estimates of these variables are found in Tables C.13 through C.23.

Quasi-continuous variables on the file are PCTGATE, PMCARE, PMCAID, PCAPREV, PMC, PBIGCON, PCTINCX, and the 12 Section E "vignette" variables representing percentages (variables beginning with the letter "V" and *not* ending with the letter "F").

Tables D.13 through D.23 are used in the same manner as the tables for percentage estimates; that is, to use them, you must have produced mean estimates using any standard statistical package and the appropriate weight variable. From each table, you can obtain standard error estimates for means based on the population of physicians or on any subset of the population represented in the table. (Use appropriate subgroup-specific tables whenever provided.) Using the row associated with the unweighted sample size of the subset, you can obtain approximate standard errors for any weighted mean estimates for that subset.

Standard errors for means greater than 80 are not presented in the tables because the highest mean value among the variables and subgroups used for modeling was 61.4. The precision of the model-based prediction decreases for any estimates far outside the observed range.

3.2.3. National Mean Estimates of Continuous Variables

There are only six continuous variables on the Public Use File that are not identifiers, weights, sampling variables or reports of percentages (see description of "quasi-continuous" variables above). These variables are WKSWRKX, HRSMEDX, HRSPATX, HRFREEX, NPHYSX, and NASSISX.

[16] If estimates are expressed in terms of proportions, rather than percentages, simply move the decimal place for the estimate and the standard error in the table two digits to the left.

Note that these six continuous variables included on the Public Use File have undergone either top-coding or bottom-coding (see Chapter 4 for more details). Therefore, a mean based on these variables may be quite different from the mean that would be calculated using the unmasked version of the variable (available only on the Restricted Use File). Instead, you should consider collapsing these continuous variables into categories and then calculating distributional estimates (percentages falling within each of the categories).

3.2.4. Additional Information on Using Standard Error Tables

If you are interested in analyzing a physician subgroup that is defined by crossing the characteristics specifically represented in the subgroup tables (for example, PCPs in a practice with low revenue from managed care, or solo practice pediatricians), you should choose the table specific to one of the defining characteristics and then use the row associated with the sample size defined by the other characteristic.

Because the models for subgroups defined by PCP/non-PCP (PCPFLAG), practice setting (PRCTYPE), and level of revenue from managed care (PMC) were roughly comparable in terms of their predictive ability, it will not matter much which of the two (or three) appropriate subgroup tables you choose. For example, for PCPs in a practice with low revenue from managed care, you can either look at the "all PCPs" table and use the row associated with the sample size of those in a practice with low revenue from managed care, or you can look at the "low revenue from managed care" table and use the row associated with the sample size of those who are PCPs.

However, the models based on specific specialty (defined by SPECX) were not as strong, so we suggest that you use tables specific to other characteristics if you are crossing specific specialty with other table-defined characteristics. For example, for solo practice pediatricians, look at the "solo or two-person practice" table and use the row associated with the sample size of those who are pediatricians, not the other way around.

Note that, because design effects vary by variable and population subgroup, these tables do not provide optimal estimates of standard errors. Furthermore, they cannot be used for other kinds of estimates, such as regression coefficients, ratios, and weighted totals. To obtain standard errors for such estimates, you would need to use the Restricted Use File and specialized software.

Users interested in analyzing change between Round One and Round Two should refer to Chapter 2 for an explanation of how to use the standard error tables to estimate the standard error of a change estimate.

CHAPTER 4

VARIABLE CONSTRUCTION AND EDITING

The CTS Physician Survey Public Use File contains three types of variables: unedited variables, edited variables, and constructed variables created from edited or unedited variables.[17] This chapter provides a general description of the types of constructed and edited variables in the file, as well as additional details on selected variables.

The information in this chapter supplements the information provided in the "Description" field of the file's codebook. Users are encouraged to review this information along with the annotated questionnaire provided in Appendix A for a better understanding of the questionnaire structure, skip patterns, and other characteristics of the variables reported on the file.

4.1. EDITED VARIABLES

The CTS Physician Survey data were collected via computer-assisted telephone interviewing (CATI). The CATI editing functions included consistency checks and editing of some skip patterns and outlier values. This section describes the editing that followed the CATI data collection, including logical editing, imputation of missing values, and editing for confidentiality. Verbatim text responses were also reviewed and coded.

4.1.1. Logical Editing

Logical editing was performed to resolve inconsistencies among related variables and to resolve skip pattern inconsistencies. For example, question A6 (YRBGNX), pertaining to the year the physician began practicing medicine, was asked of all physicians. There were cases where the reported year in which the physician began to practice was before his/her reported year of medical school graduation. In these cases, the value for YRBGNX was changed to make it three years later than the graduation year (for primary care physicians) or five years later than the graduation year (for specialists). (As described below, after the aforementioned edits, YRBGNX and GRADYRX were recoded into five-year intervals for confidentiality reasons).

Another type of logical edit occurred when a question that should have been asked according to the skip logic was not asked. For example, when a respondent said "-8:Don't Know" to physician vignette question E9 (V60MAN, For what percentage of such patients would you recommend a PSA test?), the follow-up question E9a (V60MANF, Would you recommend a PSA test rarely, sometimes, ...?) should have been asked. If for some reason question E9a was not asked in this situation (that is, if it had been coded as "-1: Inapplicable"), the response was recoded to "-9:Not Ascertained." Logical editing also included review and resolution of inconsistencies after data imputation was performed.

[17] In general, unedited variables are those that contain the original response to a single questionnaire item.

4.1.2. Imputation of Missing Values

Missing values (other than –1's) for selected variables were imputed using unweighted and weighted sequential hot-deck imputation.[18] Variables were selected for imputation according to their level of missing data and analytic importance. Table 4.1 lists the variables selected for imputation.

Most variables had few incidences of missing values (under 4 percent). The only exceptions were income (INCOMEX and INCOMET), hours of charity care (HRFREEX), and several variables from Section G: Practice Revenue that had nonresponse rates as high as 15 percent. The Section G variables are: percent managed care (PMC), number of managed care contracts (NMCCONX), percent of revenue from Medicare (PMCARE) and Medicaid (PMCAID), percent of revenue from largest managed care contract (PBIGCON), percent of revenue paid on prepaid or capitated basis (PCAPREV), and capitated revenue for the largest managed care contract (CAPAMTC). The number of managed care contracts variable had the highest nonresponse rate at 21 percent. An imputation flag is included for most variables with imputed values. A value of "1 Imputation" for the imputation flag indicates that the value of the corresponding variable was imputed. For confidentiality reasons, imputation flags were not included for variables that were masked. The imputed variables without flags are:

- Weeks practicing medicine in 1997 (WKSWRKX)
- Hours in the previous week devoted to medically related activities (HRSMEDX)
- Hours in the previous week devoted to patient activities (HRSPATX)
- Hours in the previous month devoted to charity care (HRFREEX)
- Number of physicians in practice (NPHYSX)
- Number of assistants in practice (NASSISX)
- Number of managed care contracts (NMCCONX)
- Net income in 1997 (INCOMET)
- Percent income from bonuses (PCTINCX)

Information from the Round One Physician Survey was used to impute the group of variables with the largest number of missing values. This was performed by selecting candidate "donors" from panel physicians who had similar values for the variables in Round One.

[18] In sequential hot-deck imputation, persons with missing values, or "recipients," are linked to persons with available values, or "donors," to fill in the missing data. The donors and recipients are first classified into strata and then sorted within each strata using classification/sort variables such as gender, PCP status, and year when physician began practicing medicine. (The number of strata is limited by a minimum donor-to-recipient ratio that must be satisfied within each stratum). Donors are then assigned to recipients with similar characteristics within their stratum. In weighted hot-decking, donor and recipient weights are used to help determine the assignment of donors to recipients so that means and proportions calculated using the imputed data will equal means and proportions obtained using only donor data. In general, weighted hot-decking was performed for data with more than 5 percent missing values.

TABLE 4.1

VARIABLES SELECTED FOR IMPUTATION

Description	Variable Name
Section A:	
Multiple practice	MULTPR
Section B:	
Weeks worked	WKSWRKX
Hours worked in medical activities, patient care, and charity	HRSMEDX, HRSPATX, HRFREEX
Section C:	
Acquired practice	ACQUIRD
Ownership status	OWNPR
Number of physicians and assistants	NPHYSX, NASSISX
Section D:	
Percent of patients for whom physician is a gatekeeper	PCTGATE
Section F:	
Accepting Medicare patients	NWMCARE
Accepting Medicaid patients	NWMCAID
Accepting privately insured patients	NWPRIV
Section G:	
Percent Medicare patients	PMCARE
Percent Medicaid patients	PMCAID
Percent captitated revenue	PCAPREV
Number of managed care contracts	NMCCONX
Largest contract paid on capitated basis	CAPAMTC
Percent of practice revenue from managed care	PMC
Percent of practice revenue from largest managed care contract	PBIGCON
Section H:	
Risk adjustment of profiles	RADJ
Percent income from bonuses	PCTINCX
Income	INCOMEX, INCOMET

4.1.3. Editing for Confidentiality

Some data in the Public Use File have been manipulated or edited to ensure the confidentiality of survey respondents while maximizing the scope of data released to the public. This type of editing consisted of such steps as excluding variables and constructing new variables based on original ones. All cases of editing for confidentiality are described in the file's codebook in either the "Format" field or the "Description" field. Variables subjected to confidentiality editing have been assigned names ending with "X."

4.1.3.1. Variable Exclusion

All geographic information has been removed from the Physician Public Use File. In addition, we excluded any variables that could serve to identify an individual physician. Examples include: the type of doctor--MD or DO (doctor of Osteopathy) – and the country from where the physician graduated medical school. Survey questions or constructed variables that had very small cell sizes were also excluded because these variables may uniquely describe individual physicians. Finally, we excluded all sample design parameters and weights except for one weight to be used for making national estimates. This was done because the sample design parameters describe geographic information and the other weights are for site-specific purposes. Standard error tables are included in Appendix C and described in Chapter 3. These will allow researchers to approximate standard errors that take the sampling design into account.

4.1.3.2. Masking of Minimum and Maximum Values

Extreme and relatively rare cases that fell at the top or bottom of a distribution were recoded to a lower/higher value, which is referred to as "top"- or "bottom-coding" in the Format and Description fields in the codebook. For example, the variable corresponding to question B1 (WKSWRKX, number of weeks practicing medicine in 1997) reflects the use of bottom-coding. Reported values less than 40 have been combined into a single category, "40 (bottom code)." Physician income (INCOMET) serves as another example of this type of masking. Reported income was converted to a categorical variable with intervals of $50,000 and top-coded at $300,000. Six of the continuous analytic variables on the Public Use file have undergone either top-coding or bottom-coding. Because of this, we suggest that you consider whether a mean estimate should be computed from them. This truncation of values will affect mean estimates computed from these variables. (See Section 3.2.3).

4.1.3.3. Constructing New Variables

For confidentiality reasons, new variables were constructed by combining several original variables, by collapsing values of a categorical variable, or by collapsing values for a continuous variable into categories. When survey questions identified relatively rare populations, a new variable was constructed by combining the rare cases into one or more broad groups. For a single categorical variable, one or more values were combined.

For example, SPECX, which describes the physician's specialty, was constructed by combining the responses to questions A8 (physician's specialty) and A10 (physician's subspecialty). Responses to A8 and A10 included over 200 possible values. These specialties were collapsed into seven categories of specialty in SPECX.

Another example of a newly constructed variable that combines survey responses into categories is YRBGNX, the year the physician began medical practice. Question A6 asks for the actual year the physician began practice. We recoded the year values into five-year intervals and recoded those who began practice after 1994 as 1994 (top-coding).

Similarly, the variable TOPEMPX (type of physician employment), which corresponds to question C3, was constructed by combining categories of solo practice and two-physician practice into category 6, "2 phys & solo practice." Group model HMO and Staff model HMO were combined into category 9, "Grp model & Staff model HMO."

4.1.4. Editing Verbatim Responses

For several questionnaire items, respondents were allowed to provide "other" verbatim responses when none of the existing response categories seemed to apply. These verbatim responses are excluded from the Public Use File. Many of these were reviewed and coded into an appropriate existing or new categorical value. For example, certain "other" responses to question C2:TOPOWNX (type of ownership), were recoded to an existing response category based on the verbatim responses to that question. Other ownership and employment arrangement variables were recoded on the basis of verbatim responses. For several questionnaire items, respondents were allowed to provide verbatim responses when none of the existing response categories seemed to apply. The verbatim responses themselves are excluded from the Public Use File. They were, however, reviewed and many were coded into an existing or a new categorical value. If the verbatim was not so coded, the physician's response was recorded as "1: Other."

4.2. CONSTRUCTED VARIABLES

Constructed variables include the following:

- Weight - WTPHY4
- Other variables constructed for analytical value. These range from relatively straightforward variables that combine one or more original question items for the convenience of analysts (e.g., BDCERT, the certification or eligibility status of a physician that was constructed from four survey questions: A11, A13, A15, and A17) to more complex variables such as PMC, percent managed care revenue (and the other practice revenue variables from Section G of the survey), that is constructed from survey questions G6 through G11 and is then edited for consistency with the other practice revenue variables in the survey.

Constructed variables are indicated in the file's codebook by a value of "N/A" (Not Applicable) in the "Question" field. Information on how they were constructed appears in the "Description" field. Table 4.2 contains additional background on for some of the more complex constructions.

4.3. IDENTIFICATION, GEOGRAPHIC, AND FRAME VARIABLES

Not all variables on the Public Use File were obtained directly from survey respondents via the CATI questions. Additional variables include the physician identifier and other survey administration variables relating to demographic information from the sample frame.

The physician identifier variable on the Public Use File is called PHYSIDX.

The American Medical Association (AMA) and the American Osteopathic Association (AOA) provided some demographic information when they formed the sample frame. This information includes: IMGUSPR (foreign medical school graduate), GRADYRX (year graduated from medical school), GENDER, and BIRTHX.

4.4. ADDITIONAL DETAILS ON SELECTED SURVEY VARIABLES

Table 4.2, organized by questionnaire section, provides "helpful hints" about variables (singly or in sets), discusses a variable's relationship with other variables, and suggests when to use a specific variable. This information supplements the variable-specific details contained in the file's codebook.

TABLE 4.2

ADDITIONAL INFORMATION ON SURVEY QUESTIONS
BY QUESTIONNAIRE SECTION

Variable	Additional Information
Section A Variables: Introduction	
YRBGNX	Question A6 asks for the year that the physician began medical practice. Examination of certain responses to this question indicates that some respondents replied with the number of years in practice rather than the actual year commencing practice. For these cases, YRBGNX was set to the Interview year minus the number of years in practice (initial response to YRBGNX). For physicians who did not respond to this question or for whom his/her medical school graduation year occurred after the reported value for YRBGNX, YRBGNX was reset to graduation year + 3 for primary care physicians and graduation year + 5 for specialists. If graduation year was also missing, then YRBGNX was set to be BIRTH + 30 for primary care physicians and BIRTH + 32 for specialists. YRBGNX was converted to a 4-digit year by adding 1900 to the value for YRBGNX.
PCPFLAG	PCPFLAG is a constructed flag variable that indicates whether the physician is a primary care physician (PCPFLAG=1) or a specialist (PCPFLAG=0). The variable is constructed based on responses to questions A8, A10, A9, A9a, and A9b. PCPFLAG=1 if the physician's specialty (A8 or A10) is one of the following: Family practice (019) Geriatric medicine (020,043) General practice (023) Adolescent medicine (085, 133) OR if the physician's specialty (A8 or A10) is one of the following: Internal Medicine (042) Pediatrics (088) Internal Med-Pediatrics (137) AND the physician spends most of his/her time in this specialty (i.e., A9=1) OR if the physician is an adult specialist and spends more time practicing general internal medicine than his/her subspecialty (A9a=2 or 3) OR if the physician is a pediatric specialist and spends more time practicing general pediatrics than his/her subspecialty (A9b=2 or 3) PCPFLAG is the survey definition for primary care physician.

Variable	Additional Information
SPECX	SPECX is a constructed variable based on responses to questions A8 (physician's specialty) and A10 (physician's subspecialty). The two survey questions are combined into one variable and then divided into categories according to the type of specialty. The grouping of specialties is as follows. The numbered codes were created for the survey based on AMA and AOA physician specialty classifications. 1: Internal Medicine 042: Internal medicine 043: Geriatric medicine 085: Adolescent medicine-Family practice 2: Family/General Practice 019: Family practice 020: Geriatrics-general/family 023: General practice 3: Pediatrics 088: Pediatrics 133: Adolescent medicine 137: Internal med-pediatrics 4: Medical Specialties 001: Allergy 002: Allergy & Immunology 004: Immunology 007: Pain Management 008: Critical care-Anesthesiology 009: Cardiovascular Disease-Cardiology 012: Dermatology 015: Emergency Medicine 016: Sports Medicine-Emergency Medicine 017: Pediatric Emergency Medicine 021: Sports Medicine-Family/General Practice 022: Gastroenterology 024: Preventive Medicine 035: Diabetes 036: Endocrinology 037: Hematology 038: Hepatology 039: Cardiac Electrophysiology 040: Infectious Diseases 041: Clinical & Laboratory Immunology 044: Sports Medicine 045: Nephrology 046: Nutrition 047: Oncology 048: Rheumatology 049: Clinical Biochemical Genetics 050: Clinical Cytogenetics 051: Clinical Genetics 052: Clinical Molecular Genetics 053: Medical Genetics 054: Child Neurology 055: Clinical Neurophysiology 056: Neurology 068: Occupational Medicine 086: Pediatric Intensive Care 087: Neonatology 089: Pediatric Allergy 090: Pediatric Endocrinology 091: Pediatric Pulmonology 092: Pediatric Gastroenterology 093: Pediatric Hematology/Oncology 094: Clinical & Laboratory Immunology 095: Pediatric Nephrology 096: Pediatric Rheumatology 097: Sports Medicine (Pediatrics) 098: Pediatric Cardiology 100: Physical Medicine & Rehab 116: Pulmonary Diseases 120: Neuroradiology 128: Critical Care-Medicine 136: Hematology & Oncology 144: Pediatric Emergency Medicine 145: Pediatric Infectious Diseases 147: Pulmonary-Critical Care 150: Spinal Cord Injury 155: Osteo Manipulative Treat +1 156: Spec Prof in Osteo Manip Med 157: Sports Medicine-OMM 158: Osteo Manipulative Medicine 159: Proctology 210: Developmental Medicine

Section B Variables: Utilization of Time	
HRSMEDX	HRSMEDX is a constructed variable that defines the number of hours (during the past week) spent in medically related activities. This question could be asked up to three times in three different ways by the CATI system, checking for data consistency each time. HRSMEDX is constructed from responses to survey questions B2, B3c, and B4. If HRSPATX (the number of hours spent in direct patient activities) was greater than HRSMEDX, then HRSMEDX was imputed.
HRSPATX	HRSPATX is a constructed variable that defines the number of hours (during the past week) spent in direct patient care activities. This question could be asked up to three times in three different ways by the CATI system, checking for data consistency each time. HRSPATX is constructed from responses to survey questions B3, B3d, and B5. If HRSPATX was greater than HRSMEDX (after imputation of both variables) then HRSPATX was set equal to HRSMEDX.

TABLE 4.2

ADDITIONAL INFORMATION ON SURVEY QUESTIONS,
BY QUESTIONNAIRE SECTION
(Continued)

Variable	Additional Information
Section C Variables: Type and Size of Practice	
TOPOWNX	TOPOWNX is a constructed variable that is a corrected version of survey variable C2-type of ownership. TOPOWNX is "corrected" or edited by incorporating the response to question C9. If the physician indicated (from the response to question C9) that he/she works in a practice that is a group model HMO, then TOPOWNX was set equal to "9: Group/staff model HMO."
TOPEMPX	TOPEMPX is a constructed variable that combines information from several questions about physician type of employment into one variable. TOPEMPX combines the responses to questions C3, C3b, C3c and C9. Questions C3, C3b, and C3c ask about the type of employer for which the physician works. Question C3b had been edited based on verbatim responses. If the physician indicated (from the response to question C9) that he/she works in a practice that is a group model HMO, then TOPEMPX was set equal to "9: Group/staff model HMO." The following values for TOPEMPX were recoded to "1: Other": 1: Other 11: Other insurance 14: City, county, state government 15: Integrated health 16: Freestanding clinic 17: Physician practice management 18: Community health center 19: Management services organization (MSO) 20: Physician hospital organization (PHO) 21: Locum tenens 22: Foundation 25: Independent contractor 26: Industry clinic

TABLE 4.2

ADDITIONAL INFORMATION ON SURVEY QUESTIONS,
BY QUESTIONNAIRE SECTION
(Continued)

Variable	Additional Information
PRCTYPE	PRCTYPE is a constructed variable that summarizes the type of practice in which the physician works. It combines information about ownership and employment and is constructed as follows: 1: Solo/two physician practice — TOPOWNX=solo or two-physician practice OR TOPEMPX=solo or two-physician practice 2: Group>=three physicians — TOPOWNX=three or more physicians OR TOPEMPX=three or more physicians 3: HMO — TOPOWNX=Group model HMO or staff Model HMO OR TOPEMPX=Group model HMO or staff Model HMO 4: Medical school — TOPEMPX=Medical school or university 5: Hospital based — TOPEMPX=Nongovernment hospital OR TOPEMPX=City, county, state government AND C3a=hospital 6: Other — All other responses Note that all physicians who work for a state or local government hospital are classified as "Hospital Based" in PRCTYPE but as "Other" in TOPEMPX.
GRTYPEX	GRTYPEX is a constructed variable that combines responses to questions C2a, C3aa, and C3ca for physicians working in a group practice of 3 or more physicians. If the physician's response to C2a , C3aa or C3ca is that they are working in a single-specialty practice, then GRTYPEX=1: Single specialty. Otherwise, GRTYPEX=2: Multi-specialty.

TABLE 4.2

ADDITIONAL INFORMATION ON SURVEY QUESTIONS,
BY QUESTIONNAIRE SECTION
(Continued)

Variable	Additional Information
Section E Variables: Vignettes	
VCHOL, VCHOLF through VECZEM, VECZEMF	The vignette questions were asked of primary care physicians. The first six questions (VCHOL, VHYPER, VCHEST, VBACK, V60MAN, VVITCH) are questions geared toward treating adults. The last six questions (VENUR, VTHRT, VCOUGH, VSUPOT, V6FEVR, VECZEM) are questions geared toward treating children. If a physician treats adults only, he/she was asked the first six questions. If a physician is a pediatrician or a general primary care physician who treats only children, then he/she was asked the last six questions. If the physician treats both adults and children, then he/she was asked six questions--three adult vignette questions and three child vignette questions--that were chosen randomly from each group of six questions. The expected response to each vignette question is a percentage (For what percentage of your patients would you recommend...?). If the physician responded "-8: Don't Know" to the vignette question, he/she was then asked a follow-up question that categorized the response into general categories (6: Always, 5: Almost always, 4: Frequently, 3: Sometimes, 2: Rarely, or 1: Never). Physicians who responded "1:Never" to a follow-up question were assigned a "0" value in the vignette variable. Similarly, physicians responding "6: Always" were coded "100" in the vignette question. All of the follow-up question variable names end in "F."

TABLE 4.2

ADDITIONAL INFORMATION ON SURVEY QUESTIONS,
BY QUESTIONNAIRE SECTION
(Continued)

Variable	Additional Information
Section G Variables: Practice Revenue	
PCAPREV	PCAPREV is a constructed variable indicating the percent of the practice's total patient care revenue paid on a capitated or other prepaid basis. PCAPREV is constructed from responses to: G3, G8c, and G8g (questions that asked about percentage of practice revenue paid on a capitated or other prepaid basis). Post imputation edits were performed on this variable as follows: Capitated revenue is a subset of managed care revenue. Therefore, if PCAPREV>PMC (percent managed care revenue) and both PCAPREV and PMC were imputed, then PCAPREV was edited to be equal to PMC. If there is only one managed care contract and all managed care revenue is capitated revenue, then the capitated revenue must be equal to all managed care revenue. Therefore, if NMCCONX (number of managed care contracts)=1 **AND** PMC=PBIGCON (i.e., percent managed care revenue=percent revenue from largest man care contract) **AND** CAPAMTC (amount of capitated revenue)= "4, All" **AND** PCAPREV was imputed then PCAPREV was edited to be equal to PMC.
PMC	PMC is a constructed variable indicating the percentage of the practice's total patient care revenue obtained from managed care. PMC is constructed from responses to: G7, G8, G8b, G8f, G9a, and G9d (questions that asked about percentage of practice's revenue that comes from managed care). Capitated revenue is a subset of managed care revenue. Therefore, this variable was edited in the following way: a. If PCAPREV (percent capitated revenue)>PMC , then PMC was edited to be equal to PCAPREV. In addition, a post-imputation edit was performed: b. If PCAPREV>PMC AND PMC was imputed, but PCAPREV was not imputed, then PMC was edited to be equal to PCAPREV.

TABLE 4.2

ADDITIONAL INFORMATION ON SURVEY QUESTIONS,
BY QUESTIONNAIRE SECTION
(Continued)

Variable	Additional Information
PBIGCON	PBIGCON is a constructed variable that is the percentage of the practice revenue obtained from the practice's largest managed care contract. PBIGCON is constructed from responses to: G9, G9b, and G9e (questions that asked about the percentage of practice revenue coming from the largest managed care contract). PBIGCON was edited for consistency as follows: 1. If NMCCONX (number of managed care contracts)=0, then PBIGCON was set equal to -1: Inapplicable. If there are no managed care contracts, then the questions asking about practice revenue from the largest contract are not applicable. a. If PMC (percent managed care revenue)=0, then PBIGCON was set equal to: -1: Inapplicable. If there is no managed care, then the questions asking about practice revenue from the largest contract are not applicable. 2. If PMC>0 AND NMCCONX=1, then PBIGCON was set equal to PMC. If there is managed care revenue coming from one contract only, then the practice revenue coming from the largest contract is equal to all of the managed care revenue for the practice. 3. If PMC>0 AND PBIGCON=0 then PBIGCON was imputed. If the physician indicated that there was managed care revenue, but there was no revenue coming from the largest contract, then we imputed the value for PBIGCON. b. If PMC>0 AND NMCCONX>0 AND PBIGCON=-1: Inapplicable, then PBIGCON was imputed. If there is managed care revenue, and at least one managed care contract, and the physician's responses to the PBIGCON questions were logically skipped, then we imputed the value for PBIGCON. 4. If PMC=0 AND NMCCONX>0 AND PBIGCON=-1: Inapplicable, then PBIGCON was set equal to 0. If there is at least one managed care contract, but no managed care revenue, and the physician's responses to the PBIGCON questions were logically skipped, then the percentage of revenue coming from the largest managed care contract is 0 (even though there are contracts, there is no revenue associated with them). In addition, a post-imputation edit was performed: 5. If PMC<PBIGCON and PBIGCON was imputed, then PBIGCON was set equal to PMC. If the percentage of practice revenue coming from the largest contract is greater than the total amount of managed care revenue from the contract (as a result of imputing PBIGCON), then the revenue from the largest contract is set equal to all of the managed care revenue.

TABLE 4.2

ADDITIONAL INFORMATION ON SURVEY QUESTIONS,
BY QUESTIONNAIRE SECTION
(Continued)

Variable	Additional Information
CAPAMTC	CAPAMTC is a constructed variable that is an edited version of question G11 (how much of practice revenue from the largest managed care contract is paid on a capitated or prepaid basis?). It was edited from the original value as follows: 1. If there is no managed care revenue or if there are no managed care contracts, then CAPAMTC=-1: Inapplicable. 2. If there is managed care revenue and the physician indicates that all of it is capitated (from question G8d or PMC=PCAPREV), then CAPAMTC=4: All. 3. If there is managed care revenue (PMC>0), but no capitated revenue (PCAPREV=0), then CAPAMTC=1: None. 4. If there is one managed care contract (NMCCONX=1) and all of the managed care revenue comes from that one contract and this revenue is all capitated revenue (PCAPREV=PBIGCON=PMC), then CAPAMTC=4: All.
Section H Variables: Physician Compensation Methods & Income Level	
PCTINCX	PCTINCX is a constructed variable that is an edited version of question H9 (percent of 1997 income coming from bonuses). It is edited as follows: Physicians who responded "0: No" to H9a (EBONUS-eligible for bonuses in 1997) are assigned a value of -1: Inapplicable.

CHAPTER 5

FILE DETAILS

This chapter provides an overview of the file content and technical specifications for programmers. It also describes the variable naming and coding conventions that were used on the file and that appear in the file's codebook.

5.1. FILE CONTENT AND TECHNICAL SPECIFICATIONS

The CTS Public Use File contains 12,304 person records. The unique record identifier and sort key is the variable PHYSIDX. Variables are positioned on the file in the following order:

- Survey administration variables: this group includes identifiers and other variables associated with conducting the survey
- Variables from Sections A-H of the Physician Survey questionnaire: Variables are ordered within each section by related questionnaire item number
- Weight variable

The Public Use File is provided as an ASCII-formatted file with the following technical specifications:

File name:	CTSR2PP1.TXT
Number of observations:	12,304
Number of variables:	121
Logical record length:	273 bytes

The file contains a two-byte carriage return/line feed at the end of each record. When you are converting to a PC-SAS file, use the LRECL option to specify the record length to avoid the default PC-SAS record length. If the RECFM=V option is used, the LRECL option must be specified as the logical record length (273). If RECFM=F is used, the LRECL value must be specified as the logical record length plus two (275). Note that if the RECFM option is omitted, then the default option of RECFM=V will be used, and LRECL must be specified as the logical record length (273). When you are converting to an SPSS file, use the "FIXED" option of the DATA LIST command, and read values according to column location specified by the column position after each variable name.

The record layout for this file is provided in the file's codebook.

5.2. VARIABLE NAMING CONVENTIONS

In general, a variable name reflects the content of the variable. Names were limited to seven characters so that additional indicators could be used in subsequent Public Use File releases. For the following groups of variables, a naming convention was used to provide additional information on variable content:

- ***Imputation Flags*.** These flags indicate whether a record has an imputed value for the corresponding variable. The flag variable has the same name as the variable it describes, and includes the prefix "_". When reading the data into SPSS, imputation flags contain the prefix "I" because SPSS does not recognize the "_" character. For example, _PMC (or IPMC) is the imputation flag corresponding to the variable PMC. Refer to Chapter 4 for more information on imputation and other types of editing procedures used on the file.
- ***Weight.*** The prefix "WT" is used for the weight variable name.
- ***Masked Variables***. Names of variables that were masked for confidentiality reasons end with the value "X." The variable descriptions contained in the file's codebook indicate whether the variable was masked and provide brief details as to the type of masking performed.

A copy of the data collection instrument annotated with the names of those variables that directly correspond to a single question is provided in Appendix A.

5.3. VARIABLE CODING CONVENTIONS

The following coding conventions are used on the file:

-1 Inapplicable	Question was not asked because of skip pattern.
-7 Refused	Question was asked and respondent refused to answer.
-8 Don't Know	Question was asked and respondent did not know the answer.
-9 Not Ascertained	Value was not assigned for any other reason.

INTRO #1

Hello, Dr. **(name from "Fone" file)**, my name is __ from The Gallup Organization. A short time ago, you should have received a letter from the Robert Wood Johnson Foundation indicating that Gallup is conducting a national survey of physicians for the Foundation. The survey is part of a study of changes in the health care system in communities across the nation. It concerns how such changes are affecting physicians, their practices and the health care they provide to their patients.

The interview will take about 20 minutes and we are providing an honorarium of $25 as a small token of our appreciation to each physician who completes an interview. All the information you provide will be kept strictly confidential. It will be used in statistical analysis and reported only as group totals. I can conduct the interview now or at any time that's convenient for you.

INTRO #2

Hello, Dr. **(name from "Fone" file)**, my name is _____, from The Gallup Organization. You should have received a letter from the Robert Wood Johnson Foundation indicating that Gallup would be calling you again to participate in the second round of the study of changes in the health care systems in communities across the nation. The study concerns how these changes are affecting physicians, their practices and the health care they provide to their patients.

The interview will take about twenty minutes, and we are again providing an honorarium of $25 as a small token of our appreciation to each physician who completes an interview. All the information you provide will be kept strictly confidential. It will be used in statistical analysis and reported only as group totals. I can conduct the interview now, or at any time that's convenient for you.

A1. Are you currently a full-time employee of a federal agency such as the U.S. Public Health Service, Veterans Administration or a military service? **(Probe:)** Do you receive your paychecks from a federal agency? **(If respondent works part-time for a Federal Agency, ask:)** Do you consider this (Federal Agency) your main practice?

1 Yes - **(Continue)**

2 No - **(Skip to #A2)**

8 (DK) **(Thank and Terminate)**
9 (Refused) **(Thank and Terminate)** _____ (5/13)

(If code "1" in #A1, INTERVIEWER READ:) In this survey, we will not be interviewing physicians who are Federal employees. So it appears that we do not need any further information from you at this time, but we thank you for your cooperation. - **(Thank and Terminate)**

A2. Are you currently a resident or fellow?

1 Yes - **(Continue)**

2 No - **(Skip to #A3)**

8 (DK) **(Thank and Terminate)**
9 (Refused) **(Thank and Terminate)** _____ (5/14)

(If code "1" in #A2, INTERVIEWER READ:) In this survey, we will not be interviewing physicians who are residents or fellows. So it appears that we do not need any further information from you at this time, but we thank you for your cooperation. - **(Thank and Terminate)**

A3. During a TYPICAL week, do you provide direct patient care for at least twenty hours a week? **(If necessary, say:)** Direct patient care includes seeing patients and performing surgery. **(If necessary, say:)** INCLUDE time spent on patient record-keeping, patient-related office work, and travel time connected with seeing patients. EXCLUDE time spent in training, teaching, or research, any hours on-call when not actually working, and travel between home and work at the beginning and end of the work day.

1 Yes - **(Skip to "Note" before #A3a)**

2 No - **(Continue)**

8 (DK) **(Thank and Terminate)**
9 (Refused) **(Thank and Terminate)** _____ (5/15)

(If code "2" in #A3, INTERVIEWER READ:) In this survey, we will not be interviewing physicians who typically provide patient care for less than 20 hours a week. So it appears that we do not need any further information from you at this time, but we thank you for your cooperation. - **(Thank and Terminate)**

(If code "1" or "3" in S1c, Continue; Otherwise, Skip to #A4)

A3a. Thinking back to April, 1996, at that time, were you a full-time employee of a federal agency?

1 Yes
2 No
8 (DK)
9 (Refused) _____ (21/15)

A3b. In April, 1996, were you a resident or fellow?

1 Yes
2 No
8 (DK)
9 (Refused) _____ (21/16)

A3c. In April, 1996, were you providing direct patient care for at least twenty hours a week?

1 Yes
2 No
8 (DK)
9 (Refused) _____ (21/17)

A4. Do you currently provide patient care in one practice, or more than one practice? **(If necessary, say:)** We consider multiple sites or offices associated with the same organization to be only one practice. **(INTERVIEWER NOTE #1: Examples are: a private MD with a downtown and suburban office is one practice; a regional organization with member doctors practicing in numerous satellite clinics or offices is one practice; and multiple sites with DIFFERENT organizations are different practices.) (INTERVIEWER NOTE #2: Do not count non-patient-care activity, such as teaching or administrative jobs, as practices.)**

_____ _____
(5/26 - 5/28)

(If code "003", "005-007", "013-014", "018", "025", "028", "057", "099", "103-115", "117-123", "129-131", "135", "138-143", "148-149", "160-162" or "209" in #A8,

INTERVIEWER READ:) In this survey, we are only interviewing physicians in certain specialties, and your specialty is not among those being interviewed. So, it appears that we do not need any further information from you at this time, but we thank you for your cooperation. - **(Thank and Terminate)**

(If code "042", "088" or "137" in #A8, Continue;
If code "001-002", "004", "009", "012", "015-016", "020-022", "024", "035-041", "043-048", "055-056", "085", "116", "128", "136" or "147" in #A8, Skip to #A9a;
If code "017", "049-054", "063", "086-087", "089-094", "095-098", "133" or "144-145" in #A8, Skip to #A9b;
Otherwise, Skip to #A15)

A9. **(If code "042", "088" or "137" in #A8, ask:)** Do you spend more hours weekly in general **(response in #A8)**, or a subspecialty in **(response in #A8)**? **(INTERVIEWER NOTE: If respondent says "50/50 split", code as "1")**

1 General - **(Skip to #A15)**

2 Subspecialty (including adolescent medicine or geriatrics) - **(Skip to #A10)**

8 (DK) **(Skip to #A15)**
9 (Refused) **(Skip to #A15)** _____ (5/29)

A9a. **(If code "001-002", "004", "009", "012", "015-016", "020-022", "024", "035-041", "043-048", "055-056", "085", "116", "128", "136" or "147" in #A8, ask:)** Do you spend most of your time practicing in **(response in #A8)**, or in general internal medicine? **(INTERVIEWER NOTE: If respondent says "50/50 split", code as "1")**

1 Subspecialty
2 General internal medicine (or general family practice)
3 General pediatrics
8 (DK)
9 (Refused) _____ (12/80)

(All in #A9a, Skip to #A15)

A9b. **If code "017", "049-054", "063", "086-087", "089-098", "133" or "144-145" in #A8, ask:)** Do you spend most of your time practicing in **(response in #A8)**, or in general pediatrics? **(INTERVIEWER NOTE: If respondent says "50/50 split", code as "1")**

1 Subspecialty
2 General internal medicine (General Family Practice)
3 General pediatrics
8 (DK)
9 (Refused) _____ (8/77)

(All in #A9b, Skip to #A15)

A10. **(If code "2" in #A9, ask:)** And what is that subspecialty? **(If "More than one", say:)** We're interested in the one in which you spend the most hours weekly. (Open ended **and code from hard copy)** **(CHECK SPELLING)**

(INTERVIEWER READ:) I am going to read a description of a patient and I'll ask about a possible test, treatment, or recommendation. We want you to think about patients with similar problems you've seen in your own practice during the past twelve months. The key question I'll ask is for what percentage of the patients with that problem would you recommend the test, treatment, or evaluation? Reasons for not recommending the treatment may include feeling that no treatment, or that an alternative treatment, is a better option. Any percentage, from zero to 100 percent, is a valid response.

(If code "2" or "8-9" in #A4, say:) As you answer, please think only about your main practice.

(If code "2" in "FORM", Skip to #E11; Otherwise, Continue)

E1. **(If code "1" or "3" in "FORM", ask:)** What about treating an elevated cholesterol with oral agents for a 50 year old man who has no other cardiac risk factors except elevated cholesterol? After six months on a low cholesterol diet, his total cholesterol is 240 and his LDL is 150. His HDL cholesterol is 50, giving a ratio of total cholesterol to HDL cholesterol of 4.8. For what percentage of such patients would you recommend oral agents at this point? (Open ended **and code actual percent)** **(Probe:)** Your best estimate will be fine. **(If necessary, say:)** Consider all your patients with similar clinical descriptions.

PHYSICIAN COMPENSATION METHODS AND INCOME LEVEL

(If code "1" in #C1, AND code "06" in #C2, Skip to #H9; Otherwise, Continue)

(INTERVIEWER READ:) Now, I'm going to ask you a few questions about how the practice compensates you personally.

(If code "2" or "8-9" in #A4, say:) Again, please answer only about the main practice in which you work.

H1. Are you a salaried physician?

SALPAID

1 Yes - **(Skip to #H3)**

2 No **(Continue)**
8 (DK) **(Continue)**
9 (Refused) **(Continue)**

(10/30)

H2. **(If code "2", "8" or "9" in #H1, ask:)** Are you paid in direct relation to the amount of time you work, such as by the shift or by the hour?

SALTIME

1 Yes - **(Skip to #H4)**

2 No **(Skip to #H7)**
8 (DK) **(Skip to #H7)**
9 (Refused) **(Skip to #H7)**

_____ (10/31)

H3. **(If code "1" in #H1, ask:)** Is your base salary a fixed amount that will not change until your salary is re-negotiated or is it adjusted up or down during the present contract period depending on your performance or that of the practice? **(If necessary, say:)** Adjusted up or down means for example, some practices pay their physicians an amount per month that is based on their expected revenue, but this amount is adjusted periodically to reflect actual revenue produced. **(INTERVIEWER NOTE: Base salary is the fixed amount of earnings, independent of bonuses or incentive payments.)**

SALADJ

1 Fixed amount - **(Continue)**

2 Adjusted up or down - **(Skip to #H7)**

8 (DK) **(Continue)**
9 (Refused) **(Continue)**

(10/32)

H4. **(If code "1" in #H2, OR code "1" or "8-9" in #H3, ask:)** Are you also currently eligible to earn income through any type of bonus or incentive plan? **(INTERVIEWER NOTE: Bonus can include any type of payment above the fixed, guaranteed salary.)**

BONUS

1 Yes
2 No
8 (DK)
9 (Refused)

_____ (10/33)

H5. I am going to read you a short list of factors that are sometimes taken into account by medical practices when they determine the compensation paid to physicians in the practice. For each factor, please tell me whether or not it is EXPLICITLY considered

(If code "1" in #H1, AND code "2" or "8-9" in #H4, ask:) When your salary is determined, does the **(response in #CA)** consider **(read A-D)**?

(If code "1" in #H1 AND code "1" in #H4, ask:) When either your base salary or bonus is determined, does the **(response in #CA)** consider **(read A-D)**?

(If code "1" in #H2, AND code "2", "8" or "9" in #H4, ask:) When your pay rate is determined, does the **(response in #CA)** consider **(read A-D)**?

(If code "1" in #H2, AND code "1" in #H4, ask:) When either your pay rate or bonus is determined, does the **(response in #CA)** consider **(read A-D)**?

1 Yes
2 No
8 (DK)
9 (Refused)

A. Factors that reflect your own productivity **(If necessary, say:)** Examples include the amount of revenue you generate for the practice, the number of relative value units you produce, the number of patient visits you provide, or the size of your enrollee panel
(10/34)

B. Results of satisfaction surveys COMPLETED BY YOUR OWN PATIENTS _____ (1

C. Specific measures of quality of care, such as rates of preventive care services for your patients _____ (1

H5. (Continued:)

D. Results of practice profiling comparing your pattern of using medical resources to treat patients with that of other physicians **(INTERVIEWER NOTE: A practice profile is a report that is usually computer generated, which compares you to other physicians on things like referrals to specialists, hospitalizations and other measures of cost effectiveness.)**

(If code "2", "8" or "9" in #H5-D, Skip to #H9; Otherwise, Continue)

H6. **(If code "1" in #H5-D, ask:)** Are these profiles risk-adjusted to consider the health status of your patients or the severity of their illnesses? **(INTERVIEWER NOTE: Other than by age and gender)**

Appendix B

Derivation of Standard Error Look-up Tables

APPENDIX B

DERIVATION OF STANDARD ERROR LOOK-UP TABLES

The standard errors in the tables in Appendix C were derived as follows.[1]

B.1. PERCENTAGES

To calculate standard errors for percentages (Tables C.1 through C.12), a representative set of categorical variables from the CTS Physician Survey was selected. These representative variables can be grouped into the following categories:

- Practice type and ownership: PRCTYPE, MULTPR, C5OWNER,[2] OWNPR, NWMCAID
- Board certification: BDCERT
- Compensation: ELIGBON, SALWAGE[3]
- Opinion questions: CARSAT, CLNFREE, CMPEXPC, EFGUIDE, EFPROFL, EFSURV, HIGHCAR, NEGINCN, OBHOSP, OBOUTPT, SQUAL

These variable names (other than the compensation variables) can be cross-referenced in the CTS Physician Survey Restricted Use File Codebook.

For each categorical variable with more than two possible values, we created a series of dichotomous variables--one for each possible response. Each dichotomous variable indicates whether the respondent chose that category (value set to one) or one of the other categories (value set to zero).

Weighted percentages and associated standard errors and design effects were produced for these variables using SUDAAN software (release 7.5, SAS-callable for Windows 95 and NT, Taylor Series default option for variance estimation) for national estimates (site sample and supplemental sample combined) for 13 population subgroups:

- All physicians
- All primary care physicians (PCPFLAG=1)

---

[1]The methods used were based on those described in "Sample Design, Sampling Weights, Imputation, and Variance Estimation in the 1995 National Survey of Family Growth," *Vital and Health Statistics*, Series 2, No. 124, February 1998, National Center for Health Statistics.

[2]This variable underwent masking for the Public Use File and is included as C5OWNX.

[3]These two variables were not included on the file in their original forms due to confidentiality considerations. The variables BONUS, SALPAID, SALTIME, and SALADJ, included on both the Restricted and Public Use Files, provide compensation information.

- All non-primary care physicians (PCPFLAG=0)
- Internal medicine physicians (SPECX=1)
- Family/general practice physicians (SPECX=2)
- General pediatricians (SPECX=3)
- Medical specialists, including psychiatrists (SPECX=4,6)
- Surgical specialists, including OB-GYNs (SPECX=5,7)
- Physicians in solo or two-person practice (PRCTYPE=1)
- Physicians in group practice of three or more (PRCTYPE=2)
- Physicians in other practice settings (PRCTYPE=3,4,5,6)
- Physicians in practice with managed care revenue above the median value for PMC
- Physicians in practice with managed care revenue at or below the median value for PMC

The output from the SUDAAN runs was then saved in several data files, which were used to derive regression models in SAS. The goal here was to derive a generalized function to predict design effects, given the size of the estimate and the unweighted sample size.

Before these models were run, estimates with an unweighted sample size of less than 100, a relative standard error of greater than 0.3,[4] or a particularly small or large design effect[5] were flagged as outliers and excluded from the regression runs. For the remaining estimates, a $\log_{10}$ transformation was used for the point estimate (p), for its complement ($q=1-p$), for the design effect ($DEFF$), and for the unweighted sample size (n_u).

A series of linear regression models (SAS's PROC REG) was fit, using the categorical variables specified above. If the model was not significant (at $\alpha=.10$) with all three independent variables, or if the model was significant but any of the three coefficients was not significant (at $\alpha=.10$), independent variables were dropped until the best model was fit.[6] The models were specified as:

$$\hat{D} = \log_{10}(DEFF) = b_o + b_1 \log_{10}(n_u) + b_2 \log_{10}(p) + b_3 \log_{10}(q).$$

[4]The relative standard error is calculated as the standard error of an estimate divided by the estimate. It is used as a measure of the instability of an estimate.

[5]If greater than 16 or less than 0.8.

[6]These models predict design effects with less error than that which occurs when one simply uses a mean or median design effect; however, their predictive power is relatively low. To estimate design effects with greater confidence, you would need to use the Restricted Use File with specialized software to calculate them directly.

These models were run for categorical variables (excluding outliers) for the 13 population subgroups described above.

For national estimates, the models for family/general practice physicians, general pediatricians, medical specialists, and physicians in practice with managed care revenue below the median were not significant, so the mean design effect was used in the tables.

The predicted design effect $\hat{D}EFF = 10^{\hat{D}}$ is the anti-log of the predicted $\log_{10}$ design effect $\hat{D}$ based on the associated regression model. This design effect $\hat{D}EFF$ was then used in the following standard error formula to produce the tables:

$$S.E.(p) = \sqrt{\frac{p \cdot q \cdot \hat{D}EFF}{n_u - 1}} .$$

B.2. MEANS OF QUASI-CONTINUOUS VARIABLES

As described in Chapter 3, "quasi-continuous" variables are those with responses that are expressed in terms of percentages and whose values are therefore bounded by 0 and 100. To calculate standard errors for these means (Tables C.13 through C.23), the following representative set of quasi-continuous variables from the CTS physician survey was selected:

- Percent values from vignettes: VCOUGH, VHYPER
- Percent of patients for whom physician is a gatekeeper: PCTGATE
- Percent income, payments, revenue from various sources: PMC, PBIGCON, PCAPREV, PMCARE, PMCAID, PCTINCN[7]

These variable names can be cross-referenced in the CTS Physician Survey Codebook.

Weighted means and associated standard errors and design effects were produced for these variables using SUDAAN software for the same combinations of estimate types and population subgroups described above for percentage estimates.

The goal for the quasi-continuous variable means was to derive a generalized function to predict standard errors, given the unweighted sample size and the weighted mean.

Before these models were run, estimates with an unweighted sample size of less than 100, a relative standard error of greater than 0.3, or a particularly small or large design effect[8] were flagged as outliers and excluded from the regression runs. For the remaining estimates, a $\log_{10}$

[7]This variable underwent masking for the Public Use File and is included as PCTINCX.

[8]If greater than 16 or less than 0.8.

transformation was used for the standard error (*SE*), for the unweighted sample size (n_u) and for the weighted mean ($mean_w$).

A series of linear regression models was fit, using the quasi-continuous variables specified above. The models were specified as:

$$\hat{S} = \log_{10}(SE) = b_o + b_1 \log_{10}(n_u) + b_2 \log_{10}(mean_w).$$

For national estimates, the models for non-primary care physicians and surgical specialists were not significant. For the remaining subgroups, standard errors were derived as the anti-log of the predicted log10 standard error, Shat, based on the associated regression model:

$$\hat{SE} = 10^{\hat{S}}.$$

B.3. MEANS OF OTHER CONTINUOUS VARIABLES

To calculate standard errors for means of continuous variables *other* than those described as "quasi-continuous" above, we present formulas in Chapter 3. To derive these formulas, the following representative set of continuous variables from the CTS physician survey was selected:

- How practice hours spent: HRFREE, HRSPAT, HRSMED
- Practice characteristics: NPHYS, NASSIST
- Weeks worked: WKSWRKC

All of these variables underwent masking for the public use file and are included as variables with similar names but which end in "X." These variable names can be cross-referenced in the CTS Physician Survey Codebook.

Weighted means and associated standard errors and design effects were produced for these variables using SUDAAN software for the same 13 population subgroups described above for percentage estimates.

The goal for the continuous variable means was to derive a generalized function to predict relative standard errors,[9] given the unweighted sample size and weighted mean.

Before these models were run, estimates with an unweighted sample size of less than 100 (national) or 80 (site), a relative standard error of greater than 0.3, or a particularly small or large design effect[10] were flagged as outliers and excluded from the regression runs. For the remaining estimates, a $\log_{10}$ transformation was used for the relative standard error (*RSE*), for the unweighted sample size (n_u), the weighted sample size (n_w), and for the weighted mean ($mean_w$).

[9] The relative standard error is calculated as the standard error of the estimate divided by the estimate. It is used as a measure of the instability of an estimate.

[10] If greater than 16 or less than 0.8.

A series of linear regression models was fit, using the continuous variables specified above. The models were specified as:

$$\hat{R} = \log_{10}(RSE) = b_0 + b_1 \log_{10}(n_u) + b_2 \log_{10}(mean_w),$$

or

$$\hat{R} = \log_{10}(RSE) = b_0 + b_1 \log_{10}(n_w) + b_2 \log_{10}(mean_w)$$

These models were run for continuous variables (excluding outliers) for the 13 population subgroups described above. For national estimates based on the combined sample, and for site-specific estimates, the only subgroup models that were significant were for PCPs and non-PCPs. As described in Chapter 3, predicted relative standard errors for mean estimates can then be used to estimate standard errors using the following formula:

$$\hat{SE} = mean_w \cdot 10^{\hat{R}}$$

B.4. OUTLIERS

If the number of observations used in your estimate is less than 500, your estimate is likely to be unstable, and you should not use the relevant table in Appendix C to obtain an estimate of the standard error.
